# A PDE APPROACH TO SMALL STOCHASTIC PERTURBATIONS OF HAMILTONIAN FLOWS 

HITOSHI ISHII ${ }^{\mathrm{A}, *, 1}$ AND PANAGIOTIS E. SOUGANIDIS ${ }^{\mathrm{B}, 2}$

#### Abstract

In this note we present a unified approach, based on pde methods, for the study of averaging principles for (small) stochastic perturbations of Hamiltonian flows in two space dimensions. Such problems were introduced by Freidlin and Wentzell and have been the subject of extensive study in the last few years. When the Hamiltonian flow has critical points, it exhibits complicated behavior near the critical points under a small stochastic perturbation. Asymptotically the slow (averaged) motion takes place on a graph. The issues are to identify both the equations on the sides and the boundary conditions at the vertices of the graph. In their original work Freidlin and Wentzell, using probabilistic techniques, considered perturbations by Brownian motions, while later Freidlin and Weber studied, combining probabilistic and analytic techniques based on hypoelliptic operators, a special degenerate case. Recently Sowers revisited the uniformly elliptic case and constructed what amounts to approximate correctors for the averaging problem. Our approach is based on pde techniques, works for both cases and, as a matter of fact, applies to more general degenerate anisotropic elliptic operators.

## 1. Introduction

In this note we present a unified approach, based on pde methods, for the study of averaging principles for (small) stochastic perturbations of Hamiltonian flows in two space dimensions. Such problems were introduced by Freidlin and Wentzell and have been the subject of extensive study in the last few years. When the Hamiltonian flow has critical points, it exhibits complicated behavior near the critical points under a small stochastic perturbation. Asymptotically the slow (averaged) motion takes place on a graph. The issues are to identify both the equations on the sides and

[^0]the boundary conditions at the vertices of the graph. In their original work Freidlin and Wentzell [4], using probabilistic techniques, considered perturbations by Brownian motions, while later Freidlin and Weber [3] studied, combining probabilistic and analytic techniques based on hypoelliptic operators, a special degenerate case. More recently Sowers [6,5] revisited the nondegenerate problem and constructed what amounts to approximate correctors for the averaging problem. Although natural, finding such correctors involves serious technical difficulties near the critical points.

In this note we consider anisotropic, possibly degenerate perturbations, thus generalizing significantly the previously known results. Using entirely pde-techniques, we provide a considerably simpler and unified approach to study the problem. After the statement of the problem we explain our strategy and discuss the new ideas we are introducing here.

We begin by describing the general setting and introducing the necessary material to state the asymptotic problem we are interested in.

We are given a Hamiltonian function

$$
\begin{equation*}
H \in C^{4}\left(\mathbb{R}^{2}\right) \quad \text { such that } \quad \lim _{|x| \rightarrow \infty} H(x)=\infty \tag{1.1}
\end{equation*}
$$

with exactly three nondegenerate critical points $z_{1}, z_{2}$ and $z_{3}$. Although it is possible to consider more critical points, to keep the presentation simpler here we restrict to the case of only three. More precisely, we assume that

$$
\left\{\begin{array}{l}
\text { there exist } z_{1}, z_{2}, z_{3} \in \mathbb{R}^{2} \text { such that }  \tag{1.2}\\
D H\left(z_{1}\right)=D H\left(z_{2}\right)=D H\left(z_{3}\right)=0 \text { and } D H(z) \neq 0 \text { in } \mathbb{R}^{2} \backslash\left\{z_{1}, z_{2}, z_{3}\right\}, \\
\max \left(H\left(z_{1}\right), H\left(z_{3}\right)\right)<H\left(z_{2}\right), \text { and the matrices } \\
D^{2} H\left(z_{1}\right) \text { and } D^{2} H\left(z_{3}\right) \text { are positive definite and } \operatorname{det} D^{2} H\left(z_{2}\right)<0,
\end{array}\right.
$$

and, to simplify the notation, henceforth we choose

$$
z_{2}=0 \quad \text { and } \quad H(0)=0
$$

It follows from Morse theory (see [1]) that, for any $h>0$, the open set $\left\{x \in \mathbb{R}^{2}\right.$ : $H(x)<h\}$ is connected and the open set $\left\{x \in \mathbb{R}^{2}: H(x)<0\right\}$ has exactly two connected components $D_{1}$ and $D_{3}$ such that $z_{1} \in D_{1}$ and $z_{3} \in D_{3}$.

Next we choose $h_{1}, h_{2}, h_{3} \in \mathbb{R}$ such that

$$
H\left(z_{1}\right)<h_{1}<0, \quad 0=H\left(z_{2}\right)<h_{2} \quad \text { and } \quad H\left(z_{3}\right)<h_{3}<0
$$

we consider the open sets
$\Omega_{2}=\left\{x \in \mathbb{R}^{2}: 0<H(x)<h_{2}\right\}$, and, for $i \in\{1,3\}, \Omega_{i}=\left\{x \in D_{i}: h_{i}<H(x)<0\right\}$, their "outer" boundaries

$$
\partial_{\text {out }} \Omega_{i}=\left\{x \in \bar{\Omega}_{i}: H(x)=h_{i}\right\},
$$

as well as the intervals

$$
J_{2}=\left(0, h_{2}\right) \text { and, for } i \in\{1,3\}, J_{i}=\left(h_{i}, 0\right),
$$

and, finally, for $i \in\{1,2,3\}$ and $h \in \bar{J}_{i}$, the "loops"

$$
c_{i}(h)=\left\{x \in \bar{\Omega}_{i}: H(x)=h\right\} .
$$

The pde we study is set in the connected (a simple argument justifies the last observation) set

$$
\Omega=\left\{x \in \mathbb{R}^{2}: H(x)=0\right\} \cup\left(\cup_{i=1}^{3} \Omega_{i}\right),
$$

with boundary

$$
\partial \Omega=\partial_{\mathrm{out}} \Omega_{1} \cup \partial_{\mathrm{out}} \Omega_{2} \cup \partial_{\mathrm{out}} \Omega_{3}
$$

Finally, hence to forth, we write

$$
\begin{equation*}
b=\bar{D} H=\left(H_{x_{2}},-H_{x_{1}}\right), \tag{1.3}
\end{equation*}
$$

where the subscript $x_{i}$ indicates the differentiation with respect to the variable $x_{i}$.
The problem we are considering here is the asymptotic behavior, as $\varepsilon \rightarrow 0$, of the solution $u^{\varepsilon}$ of the boundary value problem

$$
\left\{\begin{array}{l}
-\operatorname{div}\left(A D u^{\varepsilon}\right)-\left(b_{0}+\varepsilon^{-1} b\right) \cdot D u^{\varepsilon}=g \quad \text { in } \quad \Omega  \tag{1.4}\\
u^{\varepsilon}=\rho^{\varepsilon} \quad \text { on } \quad \partial \Omega .
\end{array}\right.
$$

We do not know if, in the generality described below, problem (1.4) has a unique solution or not. In this note we do not address this issue but rather we concentrate on the asymptotic analysis.

We assume that

$$
\left\{\begin{array}{l}
\rho^{\varepsilon} \in C(\partial \Omega) \text { and, for each } i \in\{1,2,3\}, \text { there exists a constant } d_{i}  \tag{1.5}\\
\text { such that, in the limit } \varepsilon \rightarrow 0, \rho^{\varepsilon} \rightarrow d_{i} \text { uniformly on } \partial_{\text {out }} \Omega_{i},
\end{array}\right.
$$

$$
\begin{equation*}
A(x)=\left(a_{i j}\right)_{1 \leq i, j \leq 2} \text { is a smooth, symmetric, nonnegative matrix, } \tag{1.6}
\end{equation*}
$$

$$
\begin{equation*}
b_{0} \text { is a smooth vector field, } \tag{1.7}
\end{equation*}
$$

$$
\left\{\begin{array}{c}
\text { for } i \in\{1,2,3\} \text { and } h \in \bar{J}_{i} \backslash\{0\}, \text { there exists } x_{i h} \in c_{i}(h) \text { such that }  \tag{1.8}\\
\\
A\left(x_{i h}\right) D H\left(x_{i h}\right) \cdot D H\left(x_{i h}\right)>0,
\end{array}\right.
$$

and

$$
\left\{\begin{array}{l}
\text { in a local orientation-preserving coordinate system at the origin, }  \tag{1.9}\\
\text { where } D^{2} H(0)=\left(\begin{array}{ll}
0 & 1 \\
1 & 0
\end{array}\right), a_{11}(0)>0 \text { and } a_{22}(0)>0
\end{array}\right.
$$

A change of variables is orientation-preserving if its Jacobian is everywhere positive. A coordinate system is orientation-preserving if it is obtained from the original coordinate system by an orientation-preserving change of variables. We remark (see Appendix) that the form of (1.4) as well as the conditions (1.8) and (1.9) are invariant under any orientation-preserving change of variables.

Regarding (1.9), we note that the Morse lemma (see [1]) yields, after a $C^{2}$-orientation preserving change of variables which fixes the origin, some $\kappa>0$ such that

$$
\begin{equation*}
H\left(x_{1}, x_{2}\right)=x_{1} x_{2} \quad \text { in } S_{\kappa}=\left\{x \in \mathbb{R}^{2}: \max \left\{\left|x_{1}\right|,\left|x_{2}\right|\right\} \leq \kappa\right\} \subset \Omega \tag{1.10}
\end{equation*}
$$

and, in these local coordinates,

$$
D^{2} H(0)=\left(\begin{array}{ll}
0 & 1 \\
1 & 0
\end{array}\right)
$$

For future reference we write

$$
\left|D_{0} H\right|=\left(a_{11} H_{x_{1}}^{2}+\left(a_{12}+a_{21}\right) H_{x_{1}} H_{x_{2}}+a_{22} H_{x_{2}}^{2}\right)^{1 / 2}=(A D H \cdot D H)^{1 / 2},
$$

and, for a smooth $\phi$,

$$
\Delta_{0} \phi=\operatorname{div}(A D \phi)=\left(a_{11} \phi_{x_{1}}+a_{12} \phi_{x_{2}}\right)_{x_{1}}+\left(a_{21} \phi_{x_{1}}+a_{22} \phi_{x_{2}}\right)_{x_{2}}
$$

To state the result, we need some additional preliminary material. To this end, we consider the initial value problem (Hamiltonian system)

$$
\begin{equation*}
\dot{X}(t)=\bar{D} H(X(t)) \quad \text { and } \quad X(0)=x \in \mathbb{R}^{2} \tag{1.11}
\end{equation*}
$$

which admits a unique global in time solution $X(t, x)$. Note that, in view of (1.1),
$X, \dot{X} \in C^{3}\left(\mathbb{R} \times \mathbb{R}^{2} ; \mathbb{R}^{2}\right) \quad$ and $\quad H(X(t, x))=H(x) \quad$ for all $\quad(t, x) \in \mathbb{R} \times \mathbb{R}^{2}$.
Fix $i \in\{1,2,3\}$ and $h \in \bar{J}_{i} \backslash\{0\}$. Since $X(\mathbb{R}, x)=\{X(t, x): t \in \mathbb{R}\} \subset c_{i}(h)$ if $x \in c_{i}(h)$, and $\bar{D} H(x) \neq 0$ for all $x \in c_{i}(h)$, it is easily seen that the map $t \mapsto X(t, x)$ is periodic in $t$ for all $x \in c_{i}(h)$.

It follows from the geometry of the domains $\Omega_{i}$ 's that, for any $x \in c_{i}(h)$ and $h \neq 0$,

$$
\begin{equation*}
c_{i}(h)=X(\mathbb{R}, x), \tag{1.12}
\end{equation*}
$$

and, moreover,

$$
\left\{\begin{array}{l}
\text { the minimal period } T_{i}(h) \text { of } X(\mathbb{R}, x) \text { is independent of } x \in c_{i}(h)  \tag{1.13}\\
\text { and } 0<T_{i}(h)<\infty .
\end{array}\right.
$$

Throughout the paper, for $i=1,3$, we fix $p_{i} \in c_{i}(0) \backslash\{0\}$ and we denote by $Y_{i}(h)$ the solution of the initial value problem

$$
\begin{equation*}
Y_{i}^{\prime}(h)=\frac{D H\left(Y_{i}(h)\right)}{\left|D H\left(Y_{i}(h)\right)\right|^{2}} \quad \text { and } \quad Y_{i}(0)=p_{i} \tag{1.14}
\end{equation*}
$$

where $Y_{i}^{\prime}(h)=d Y_{i}(h) / d h$, and we set

$$
l_{i}=\left\{Y_{i}(t): t \in\left[h_{i}, h_{2}\right]\right\} .
$$

It is immediate that

$$
H\left(Y_{i}(h)\right)=h \quad \text { for all } \quad h \in\left[h_{i}, h_{2}\right] \quad \text { and } \quad Y_{i} \in C^{3}\left(\left[h_{i}, h_{2}\right] ; \mathbb{R}^{2}\right)
$$

To simplify the presentation, we introduce $Y_{2}$ and $l_{2}$ as well just by setting either $\left(Y_{2}, l_{2}\right)=\left(Y_{1}, l_{1}\right)$ or $\left(Y_{2}, l_{2}\right)=\left(Y_{3}, l_{3}\right)$.

In the sequel we make several observations and statements which hold true for all $i \in\{1,2,3\}$. To avoid repeating the latter, henceforth, in all statements which hold for all the $i$ 's, we will simply write $i$.

Let $\Phi_{i}: \mathbb{R} \times \bar{J}_{i} \rightarrow \mathbb{R}^{2}$ be given by $\Phi_{i}(t, h)=X\left(t, Y_{i}(h)\right)$. It follows that $\Phi_{i} \in$ $C^{3}\left(\mathbb{R} \times \bar{J}_{i}\right)$ and, since $H\left(\Phi_{i}(t, h)\right)=h$ for all $(t, h) \in \mathbb{R} \times \bar{J}_{i}$,

$$
\begin{equation*}
\operatorname{det} D \Phi_{i}=1 \quad \text { on } \quad \mathbb{R} \times \bar{J}_{i} \tag{1.15}
\end{equation*}
$$

The limit of the $u^{\varepsilon}$ 's is described by the unique solution $\left(u_{1}, u_{2}, u_{3}\right) \in C\left(\bar{J}_{1}\right) \times$ $C\left(\bar{J}_{2}\right) \times C\left(\bar{J}_{3}\right)$ of the boundary value problem

$$
\left\{\begin{array}{l}
\left(T_{i} A_{i} u_{i}\right)^{\prime \prime}-\left(T_{i} B_{i} u_{i}\right)^{\prime}+\left(T_{i} B_{0 i} u_{i}\right)^{\prime}-T_{i} C_{0 i} u_{i}+T_{i} \hat{g}_{i}=0 \quad \text { in } \quad J_{i}  \tag{1.16}\\
\beta_{2} u_{2}^{\prime}(0)=\sum_{i=1,3} \beta_{i} u_{i}^{\prime}(0) \\
u_{1}(0)=u_{2}(0)=u_{3}(0) \text { and } u_{i}\left(h_{i}\right)=d_{i}
\end{array}\right.
$$

where, for $h \in J_{i}$,

$$
\left\{\begin{array}{l}
A_{i}(h)=T_{i}(h)^{-1} \int_{0}^{T_{i}(h)}\left|D_{0} H\left(\Phi_{i}(t, h)\right)\right|^{2} d t  \tag{1.17}\\
B_{i}(h)=T_{i}(h)^{-1} \int_{0}^{T_{i}(h)} \Delta_{0} H\left(\Phi_{i}(t, h)\right) d t \\
B_{0 i}(h)=T_{i}(h)^{-1} \int_{0}^{T_{i}(h)}\left(b_{0} \cdot D H\right)\left(\Phi_{i}(t, h)\right) d t \\
C_{0 i}(h)=T_{i}(h)^{-1} \int_{0}^{T_{i}(h)} \operatorname{div} b_{0}\left(\Phi_{i}(t, h)\right) d t \\
\hat{g}_{i}(h)=T_{i}(h)^{-1} \int_{0}^{T_{i}(h)} g\left(\Phi_{i}(t, h)\right) d t \\
\beta_{i}=\lim _{h \rightarrow 0+}\left(A_{i} T_{i}\right)\left((-1)^{i} h\right)
\end{array}\right.
$$

As it is shown in Section 2, (1.16) can be rewritten as

$$
\left\{\begin{array}{l}
A_{i} u_{i}^{\prime \prime}+\left(B_{i}+B_{0 i}\right) u_{i}^{\prime}+\hat{g}_{i}=0 \quad \text { in } \quad J_{i}  \tag{1.18}\\
\beta_{2} u_{2}^{\prime}(0)=\sum_{i=1,3} \beta_{i} u_{i}^{\prime}(0) \\
u_{1}(0)=u_{2}(0)=u_{3}(0) \text { and } u_{i}\left(h_{i}\right)=d_{i} .
\end{array}\right.
$$

The result is:
Theorem 1.1. Assume (1.1), (1.2), (1.5), (1.6), (1.7), (1.8), (1.9), and let $u^{\varepsilon} \in$ $C^{2}(\bar{\Omega})$ and $\left(u_{1}, u_{2}, u_{3}\right) \in\left(C^{1}\left(\bar{J}_{1}\right) \cap C^{2}\left(J_{1}\right)\right) \times\left(C^{1}\left(\bar{J}_{2}\right) \cap C^{2}\left(J_{2}\right)\right) \times\left(C^{1}\left(\bar{J}_{3}\right) \cap C^{2}\left(J_{3}\right)\right)$ be a solution of (1.4) and the unique solution of (1.16) respectively. Then, as $\varepsilon \rightarrow 0$,

$$
\begin{equation*}
u^{\varepsilon} \rightarrow u_{i} \circ H \quad \text { uniformly on } \quad \bar{\Omega}_{i} . \tag{1.19}
\end{equation*}
$$

This theorem was proved by Freidlin and Wentzell [4] for the Laplacian, i.e., $A=I$, and with slightly more general Hamiltonian $H$. (Note that our restrictions on $H$ are
motivated by the desire to keep the presentation simpler.) Freidlin and Webber [3] studied, using different techniques, a very special degenerate operator, namely $\Delta_{0} \phi=\phi_{x_{2} x_{2}}$ and a particular $H$. Finally Sowers [6, 5] considered extensions of [4] and constructed what amounts to approximate correctors.

As remarked earlier here we prove a more general result and provide a unified approach based entirely on pde methods. Our proof not only is simpler than the earlier ones but also introduces several new ideas.

Next we outline some of the key points/steps of the paper. We begin with (1.16). The fact that any uniform in $\bar{\Omega}$ limit of the $u^{\varepsilon}$ 's is a function of $H$ is due to the presence of the $\varepsilon^{-1}$ factor in front of the $b$ in (1.4). The specific form of (1.16) follows from the above observation and a more or less standard averaging argument. The condition at the vertex is a consequence of simple integration by parts given that the $u^{\varepsilon}$ 's solve (1.4) in all of $\Omega$. The heart of the argument is therefore to establish the uniform convergence. This requires uniform in $\varepsilon$ estimates, a delicate issue in view of the linearity of the equation and the fact that the matrix $A$ may be degenerate. The former affects possible $L^{\infty}$-bounds while the second comes in when trying to obtain uniform gradient bounds. In the paper we obtain the $L^{\infty}$-bounds in an indirect way. First we prove the result assuming such bounds and then we use a classical blow up argument to obtain the sup-estimates. Assuming the latter we use standard arguments from the theory of viscosity solutions and the periodicity along the trajectories of the Hamiltonian system (for $h \neq 0$ ) to prove that the largest and smallest possible limits of the $u^{\varepsilon}$ 's are solutions of the (1.16) away from the vertex. A key step here is to use (1.8) to prove a local, uniform in $\varepsilon, L^{2}$-estimate for the derivative of the $u^{\varepsilon}$ 's in a direction $e$. To find this direction we think that $-b=-\bar{D} H$ has the direction of time, and, for $x \in\{|D H| \neq 0\}$, we choose a unit vector $e \neq 0$ so that $e$ and $-b(x) \operatorname{span} \mathbb{R}^{2}$. This enables us to show that, along subsequences, the $u^{\varepsilon}$ 's converge along subsequences in $\{|D H| \neq 0\}$ to a solution of the (1.16) away from the vertex. To conclude we need to prove the convergence on $\bar{\Omega}$. For this we construct appropriate inner and outer barriers that control the behavior near the origin and $\partial \Omega$.

The paper is organized as follows. Section 2, which is divided into three parts, is devoted to the analysis of (1.16). In the first part we study some properties of the minimal periods. In the last two parts, we consider the coefficients of the ode in (1.16) and provide the general formula for the solution of (1.16). Section 3 is devoted
to the proof of Theorem 1.1. It relies on four results that we formulate as separate theorems. They are: a, uniform in $\varepsilon, L^{\infty}$-bound for the $u^{\varepsilon}$ 's (Theorem 3.1, proved in Section 3), the convergence along subsequences of the $u^{\varepsilon}$ 's on the set $\left\{\left|D_{0} H\right|>0\right\}$ (Theorem 3.2, proved in Section 4 combined with Theorem 3.1), and the existence of outer barriers and inner barriers (Theorem 3.3 and Theorem 3.4 respectively, both proved in Section 5). In the proofs we repeatedly perform orientation preserving changes of variables. We show in the Appendix that such transformations preserve the general structure of the problem. Finally we also formulate as a lemma a simple consequence of the classical Green's theorem that we use several times in the proofs.

Throughout the paper we denote by $C$ positive constants, that may change from line to line and are independent of $\varepsilon$. The latter is always taken to be positive. Moreover we use the term "solution" to mean either a classical (if smooth) or a viscosity (if only continuous) solution.

We conclude with the notation we use in the paper.
Notation: For any $a, b \in \mathbb{R}, x=\left(x_{1}, x_{2}\right) \in \mathbb{R}^{2}, f: V \rightarrow \mathbb{R}^{k}, V \subset \mathbb{R}^{m}$, symmetric matrix $A$ of order $k$, and family of bounded functions $w_{\varepsilon}: \Omega \rightarrow \mathbb{R}$ we have:

$$
\left\{\begin{array}{l}
|x|_{\infty}=\max \left\{\left|x_{1}\right|,\left|x_{2}\right|\right\}, \\
\|f\|_{\infty, V}=\sup \{|f(x)|: x \in V\}, \\
\{f>0\}=\{x \in V: f(x)>0\} \quad \text { for } k=1 \\
w^{+}(x)=\lim _{\sup } w^{\varepsilon}(x)=\lim _{\sup }^{y \rightarrow x, \varepsilon \rightarrow 0} \\
w^{\varepsilon}(y), \\
w^{-}(x)=\liminf _{*} w^{\varepsilon}(x)=\liminf _{y \rightarrow x, \varepsilon \rightarrow 0} w^{\varepsilon}(y)
\end{array}\right.
$$

## 2. The limit problem

2.1. Some properties of the minimal period. We study here the regularity and the behavior for small $h$ of the minimal periods $T_{1}, T_{2}$ and $T_{3}$. Both are necessary for the regularity of the coefficients of (1.16) as well as some other estimates later in the paper. At first passage the reader may choose to skip the proofs.

We begin with
Lemma 2.1. $T_{i} \in C^{3}\left(\bar{J}_{i} \backslash\{0\}\right)$.
Proof. Since $Y_{i} \in C^{3}\left(\bar{J}_{i}\right)$ is injective, we may choose $\phi \in C^{3}\left(\mathbb{R}^{2}\right)$ such that, for all $x \in l_{i}, \phi(x)=0$ and $D \phi(x) \neq 0$.

Set $\psi(t, h)=\phi\left(X\left(t, Y_{i}(h)\right)\right)$ for $(t, h) \in \mathbb{R} \times \bar{J}_{i}$, and note that, for all $h \in \bar{J}_{i} \backslash\{0\}$, $\psi\left(T_{i}(h), h\right)=\phi\left(Y_{i}(h)\right)=0$. Moreover, since, for any $h \in \bar{J}_{i}$, the vectors $D \phi\left(Y_{i}(h)\right)$

## A PDE APPROACH TO SMALL STOCHASTIC PERTURBATIONS OF HAMILTONIAN FLOWS 9

 and $\bar{D} H\left(Y_{i}(h)\right)$ are parallel to each other, we see that, if $h \in \bar{J}_{i} \backslash\{0\}$, then$$
\psi_{t}\left(T_{i}(h), h\right)=D \phi\left(Y_{i}(h)\right) \cdot \dot{X}\left(T_{i}(h), Y_{i}(h)\right)=D \phi\left(Y_{i}(h)\right) \cdot \bar{D} H\left(Y_{i}(h)\right) \neq 0
$$

and the claim follows from the implicit function theorem.
The small $h$ behavior of the $T_{i}$ 's is the subject of
Lemma 2.2. There exists $C>0$ such that, for all $h \in J_{i}$,

$$
\begin{equation*}
C^{-1} \log \left(|h|^{-1}+2\right) \leq T_{i}(h) \leq C \log \left(|h|^{-1}+2\right) . \tag{2.1}
\end{equation*}
$$

Proof. Since the arguments are similar we only prove (2.1) for $T_{2}$, which, for notational simplicity, we denote for the rest of the proof by $T$.

In view of (1.10), we have

$$
m=\inf \left\{|D H(x)|: x \in \Omega,|H(x)| \geq \kappa^{2} / 4\right\}>0 .
$$

Let $h \in\left(0, \kappa^{2} / 4\right)$, fix $x \in \Omega_{2}$ so that $h=H(x)$, consider the trajectory $X(t)=$ $X(t, x)$ and observe that $X(\bar{t})=\sqrt{h}(1,1) \in S_{\kappa}$ for some $\bar{t} \in[0, T(h))$. Assuming that, after a translation, $X(0)=\sqrt{h}(1,1)$, we find that $X(t)=\sqrt{h}\left(e^{t}, e^{-t}\right)$ for all $t \in[0, \tau]$ with $\tau>0$ given by $\sqrt{h} e^{\tau}=\kappa$. It is then clear that $\tau<T(h)$ and, hence,

$$
\begin{equation*}
T(h)>\log \left(\kappa h^{-1 / 2}\right) \quad \text { for } \quad 0<h<\kappa^{2} / 4 . \tag{2.2}
\end{equation*}
$$

If $\operatorname{diam}(B)$ denotes the diameter of the set $B$, we have
$2 \operatorname{diam}\left(c_{2}(0)\right) \leq 2 \operatorname{diam}\left(c_{2}(h)\right) \leq \int_{0}^{T(h)}|\dot{X}| d t=\int_{0}^{T(h)} \overline{|D H(X)| d t \leq T(h) \sup _{\Omega}|D H|, ~}$ and, thus,

$$
T(h) \geq 2\left(\sup _{\Omega}|D H|\right)^{-1} \operatorname{diam}\left(c_{2}(0)\right)
$$

which yields, in view of (2.2), the lower bound for $T_{2}$ in (2.1).
Applying Green's theorem, for $\Delta=\partial^{2} / \partial x_{1}^{2}+\partial^{2} / \partial x_{2}^{2}$, we find

$$
\int_{\left\{h<H<h_{2}\right\}} \Delta H d x=\int_{0}^{T\left(h_{2}\right)}\left|D H\left(\Phi_{2}\left(t, h_{2}\right)\right)\right|^{2} d t-\int_{0}^{T(h)}|D H(X(t))|^{2} d t .
$$

Accordingly, if $h \geq \kappa^{2} / 4$,

$$
m^{2} T(h) \leq \int_{0}^{T(h)} \mid D H\left(\left.X(t)\right|^{2} d t \leq \int_{\Omega}|\Delta H| d x+\int_{0}^{T\left(h_{2}\right)}\left|D H\left(\Phi_{2}\left(t, h_{2}\right)\right)\right|^{2} d t\right.
$$

and, hence,

$$
\begin{equation*}
T(h) \leq m^{-2}\left(\int_{\Omega}|\Delta H| d x+\int_{c_{2}\left(h_{2}\right)}|D H| d l\right) . \tag{2.3}
\end{equation*}
$$

On the other hand, if $0<h<\kappa^{2} / 4$, then assuming, as before, that $X(0)=\sqrt{h}(1,1)$ and $\sqrt{h} e^{\tau}=\kappa$, we find

$$
\int_{\Omega}|\Delta H| d x+\int_{c_{2}\left(h_{2}\right)}|D H| d l \geq \int_{\tau}^{T(h)-\tau} \mid D H\left(\left.X(t)\right|^{2} d t \geq m^{2}(T(h)-2 \tau)\right.
$$

and, hence,

$$
\begin{aligned}
T(h) & \leq 2 \tau+m^{-2}\left(\int_{\Omega}|\Delta H| d x+\int_{c_{2}\left(h_{2}\right)}|D H| d l\right) \\
& \leq \frac{1}{2} \log \left(\kappa^{2} h^{-1}\right)+m^{-2}\left(\int_{\Omega}|\Delta H| d x+\int_{c_{2}\left(h_{2}\right)}|D H| d l\right) .
\end{aligned}
$$

Combining the above estimate and (2.3) yields, for some other $C>0$, the second inequality in (2.1) for $T_{2}$.
2.2. The coefficients of the ode in (1.16). Here we establish the properties (positivity, regularity as well as what is necessary to show (1.18)) of the coefficients of the ode in (1.16).

Applying Lemma 6.1 to

$$
f_{1}=a_{11} H_{x_{1}}+a_{12} H_{x_{2}} \quad \text { and } \quad f_{2}=a_{21} H_{x_{1}}+a_{22} H_{x_{2}},
$$

with $\alpha_{i}=T_{i}(h)$ for $h \in J_{i}$, and differentiating the resulting formula with respect by to $h$, we obtain

$$
\begin{align*}
\left(T_{i} A_{i}\right)^{\prime}(h) & =\frac{d}{d h} \int_{0}^{T_{i}(h)}\left|D_{0} H \circ \Phi_{i}(t, h)\right|^{2} d t \\
& =\frac{d}{d h} \int_{0}^{T_{i}(h)}\left(f_{1} H_{x_{1}}+f_{2} H_{x_{2}}\right) \circ \Phi(t, h) d t  \tag{2.4}\\
& =\int_{0}^{T_{i}(h)}\left(f_{1, x_{1}}+f_{2, x_{2}}\right) \circ \Phi_{i}(t, h) d t=\int_{0}^{T_{i}(h)} \Delta_{0} H \circ \Phi_{i}(t, h) d t \\
& =\left(T_{i} B_{i}\right)(h),
\end{align*}
$$

and

$$
\begin{align*}
\left(T_{i} B_{0 i}\right)^{\prime}(h) & =\frac{d}{d h} \int_{0}^{T_{i}(h)}\left|\left(b_{0} \cdot D H\right) \circ \Phi_{i}(t, h)\right|^{2} d t=\int_{0}^{T_{i}(h)} \operatorname{div} b_{0} \circ \Phi_{i}(t, h) d t  \tag{2.5}\\
& =\left(T_{i} C_{0 i}\right)(h) .
\end{align*}
$$

We have:
Lemma 2.3. $A_{i}, B_{i} \in C^{2}\left(\bar{J}_{i} \backslash\{0\}\right), A_{i}>0$, and (2.4) and (2.5) hold for all $h \in J_{i}$.

Proof. The positivity of the $A_{i}$ 's is immediate from (1.17) and (1.8), the claimed regularity follows from the fact that $T_{i} \in C^{3}\left(\bar{J}_{i} \backslash\{0\}\right)$, and the formulae were derived above.

Using (2.4) and (2.5) we find that the equation in (1.16) can be rewritten as

$$
\begin{equation*}
\left(T_{i} A_{i} u_{i}^{\prime}\right)^{\prime}+T_{i} B_{0 i} u_{i}^{\prime}+T_{i} \hat{g}_{i}=0 \quad \text { in } J_{i}, \tag{2.6}
\end{equation*}
$$

or

$$
\begin{equation*}
A_{i} u_{i}^{\prime \prime}+\left(B_{i}+B_{0 i}\right) u_{i}^{\prime}+\hat{g}_{i}=0 \quad \text { in } J_{i} . \tag{2.7}
\end{equation*}
$$

We have:
Lemma 2.4. The constants $\beta_{i}$ in (1.17) are well-defined and positive and the functions $T_{i} A_{i},\left(T_{i} A_{i}\right)^{-1}, T_{i} B_{0 i}$ and $B_{0 i} / A_{i}$ are uniformly continuous in $J_{i}$.

Proof. It is immediate from (1.17) that $A_{i}, B_{i}$ and $\hat{g}_{i}$ are bounded. Accordingly, in view of Lemma 2.2, we see that $T_{i} B_{i} \in L^{1}\left(J_{i}\right)$ and, since

$$
\left(T_{i} A_{i}\right)(h)=\left(T_{i} A_{i}\right)\left(h_{i}\right)+\int_{h_{i}}^{h}\left(T_{i} B_{i}\right)(\eta) d \eta,
$$

$T_{i} A_{i}$ is uniformly continuous in $J_{i}$ and the limits $\beta_{i}=\lim _{h \rightarrow 0+}\left(T_{i} A_{i}\right)\left((-1)^{i} h\right)$ exist.
We focus now on $T_{2} A_{2}$, since the arguments for $T_{1} A_{1}$ and $T_{3} A_{3}$ are similar. In view of (1.9) and (1.10), we may choose (by taking $\kappa>0$ small enough) constants $0<a_{0} \leq a_{1}<\infty$ such that, for $x \in S_{\kappa}$,

$$
a_{0} \leq \min \left\{a_{11}(x), a_{22}(x)\right\} \leq \max \left\{a_{11}(x), a_{22}(x)\right\} \leq a_{1}
$$

and, hence,

$$
\left|a_{12}(x)\right|=\left|a_{21}(x)\right| \leq \sqrt{a_{11}(x) a_{22}(x)} \leq a_{1} .
$$

Fix $h \in\left(0, e^{-4 a_{1} / a_{0}} \kappa^{2}\right)$, set $x=\sqrt{h}(1,1) \in V$ and $X(t)=X(t, x)$, and recall that $X(t)=\sqrt{h}\left(e^{t}, e^{-t}\right)$ for $|t| \leq \tau$, where, as before, $\sqrt{h} e^{\tau}=\kappa$.

As in the proof of Lemma 2.2, we find that $T_{2}(h)>\tau$ and, hence,

$$
\begin{aligned}
\int_{0}^{T_{2}(h)}\left|D_{0} H(X(t))\right|^{2} d t & \geq \int_{0}^{\tau}\left(a_{0} X_{2}(t)^{2}-2 a_{1}\left|X_{1}(t) X_{2}(t)\right|+a_{0} X_{2}(t)^{2}\right) d t \\
& =h \int_{0}^{\tau}\left(a_{0}\left(e^{2 t}+e^{-2 t}\right)-2 a_{1}\right) d t>\frac{a_{0} h}{2}\left(e^{2 \tau}-1\right)-2 a_{1} h \tau
\end{aligned}
$$

Noting that

$$
2 \tau=\log \frac{\kappa^{2}}{h} \geq \frac{4 a_{1}}{a_{0}} \quad \text { and } \quad e^{2 \tau}-1>2 \tau+2 \tau^{2}>2 \tau^{2} \geq \frac{8 a_{1} \tau}{a_{0}}
$$

we get

$$
\left(T_{2} A_{2}\right)(h) \geq \frac{a_{0} h}{4}\left(e^{2 \tau}-1\right)+2 a_{1} h \tau-2 a_{1} h \tau=\frac{a_{0}}{4}\left(\kappa^{2}-h\right) \geq \frac{a_{0}}{4}\left(1-e^{-\frac{4 a_{1}}{a_{0}}}\right) \kappa^{2} .
$$

Since $T_{2} A_{2}>0$ in ( $0, h_{2}$ ], we conclude that

$$
\inf _{h \in J_{2}}\left(T_{2} A_{2}\right)(h)>0 .
$$

Hence, $\beta_{i}>0$, and the function $\left(T_{i} A_{i}\right)^{-1}$ is uniformly continuous in $J_{i}$.
Similarly, we have $T_{i} C_{0 i} \in L^{1}\left(J_{i}\right)$ and

$$
\left(T_{i} B_{0 i}\right)(h)=\left(T_{i} B_{0 i}\right)\left(h_{i}\right)+\int_{h_{i}}^{h}\left(T_{i} C_{0 i}\right)(\eta) d \eta,
$$

and therefore, the function $T_{i} B_{0 i}$ is uniformly continuous in $J_{i}$.
The last claim is a consequence of the already obtained regularity.
Set

$$
\begin{equation*}
\gamma_{i}=\left(T_{i} B_{0 i}\right)(0)=\lim _{h \rightarrow 0+}\left(T_{i} B_{0 i}\right)\left((-1)^{i} h\right) . \tag{2.8}
\end{equation*}
$$

We have:
Lemma 2.5. $\quad \sum_{i=1}^{3}(-1)^{i} \beta_{i}=0 \quad$ and $\quad \sum_{i=1}^{3}(-1)^{i} \gamma_{i}=0$.
Proof. Fix $0<\varepsilon<\min \left\{(-1)^{i} h_{i}: i=1,2,3\right\}$, let $\Omega(\varepsilon)=\{x \in \Omega:|H(x)|<\varepsilon\}$, observe that $\partial \Omega(\varepsilon)$ has three connected components $c_{1}(-\varepsilon), c_{2}(\varepsilon)$ and $c_{3}(-\varepsilon)$, and note that, for $x \in c_{2}(\varepsilon), D H(x)$ points outward from $\Omega(\varepsilon)$, while, for $i=1,3$ and $x \in c_{i}(-\varepsilon), D H(x)$ points inward to $\Omega(\varepsilon)$.

Using Lemma 6.1 with $f_{1}=a_{11} H_{x_{1}}+a_{12} H_{x_{2}}$ and $f_{2}=a_{21} H_{x_{1}}+a_{22} H_{x_{2}}$, we find

$$
\begin{aligned}
\int_{\Omega(\varepsilon)} \Delta_{0} H(x) d x= & -\sum_{i=1,3} \int_{0}^{T_{i}(-\varepsilon)}\left|D_{0} H\right|^{2}\left(\Phi_{i}(t,-\varepsilon)\right) d t \\
& +\int_{0}^{T_{2}(\varepsilon)}\left|D_{0} H\right|^{2}\left(\Phi_{2}(t, \varepsilon)\right) d t
\end{aligned}
$$

Similarly we have

$$
\begin{aligned}
\int_{\Omega(\varepsilon)} \operatorname{div} b_{0}(x) d x= & -\sum_{i=1,3} \int_{0}^{T_{i}(-\varepsilon)}\left(b_{0} \cdot D H\right)\left(\Phi_{i}(t,-\varepsilon)\right) d t \\
& +\int_{0}^{T_{2}(\varepsilon)}\left(b_{0} \cdot D H\right)\left(\Phi_{2}(t, \varepsilon)\right) d t .
\end{aligned}
$$

Letting $\varepsilon \rightarrow 0$ yields the claim.
2.3. The boundary value problem for the ode. Solutions $u=\left(u_{1}, u_{2}, u_{3}\right)$ of the ode (1.18), without the boundary conditions, are given, for some constants $C_{i j}$, with $i=1,2,3, j=1,2$, by

$$
\begin{align*}
u_{i}(h)= & C_{i 1}+C_{i 2} \int_{0}^{h}\left(T_{i} A_{i}\right)(\eta)^{-1} e^{-\int_{0}^{\eta} B_{0 i}(t) A_{i}(t)^{-1}} d t d \eta  \tag{2.9}\\
& -\int_{0}^{h}\left(T_{i} A_{i}\right)(\eta)^{-1} \int_{0}^{\eta} e^{-\int_{\xi}^{\eta} B_{0 i}(s) A_{i}(s)^{-1} d s}\left(T_{i} \hat{g}_{i}\right)(\xi) d \xi d \eta
\end{align*}
$$

Using the boundary conditions of (1.18) in (2.9) we find

$$
\begin{equation*}
u_{i}(0)=C_{i 1}, \quad u_{i}^{\prime}(0)=\frac{C_{i 2}}{\left(T_{i} A_{i}\right)(0)}=\frac{C_{i 2}}{\beta_{i}} \quad \text { and } \quad u_{i}\left(h_{i}\right)=C_{i 1}+C_{i 2} P_{i}-Q_{i}, \tag{2.10}
\end{equation*}
$$

where

$$
\begin{align*}
P_{i} & =\int_{0}^{h_{i}}\left(T_{i} A_{i}\right)(\eta)^{-1} e^{-\int_{0}^{\eta} B_{0 i}(t) A_{i}(t)^{-1} d t} d \eta  \tag{2.11}\\
Q_{i} & =\int_{0}^{h_{i}}\left(T_{i} A_{i}\right)(\eta)^{-1} \int_{0}^{\eta} e^{-\int_{\xi}^{\eta} B_{0 i}(s) A_{i}(s)^{-1} d s}\left(T_{i} \hat{g}_{i}\right)(\xi) d \xi d \eta .
\end{align*}
$$

The above and the boundary conditions at the vertex in (1.18) lead to the linear system

$$
C_{11}=C_{21}=C_{31}, C_{22}=\sum_{i=1,3} C_{i 2} \text { and } C_{i 1}+C_{i 2} P_{i}-Q_{i}=d_{i}
$$

whose unique solution is given by

$$
\begin{equation*}
C_{i 1}=\frac{\sum_{i=1}^{3}(-1)^{i} P_{i}^{-1}\left(d_{i}+Q_{i}\right)}{\sum_{i=1}^{3}(-1)^{i} P_{i}^{-1}} \text { and } C_{i 2}=P_{i}^{-1}\left(d_{i}+Q_{i}-C_{i 1}\right) . \tag{2.12}
\end{equation*}
$$

## 3. The proof of the main theorem

We formulate here as theorems the steps, described in the informal discussion at the end of the Introduction, that lead to the proof of Theorem 1.1.

We have:
Theorem 3.1. (uniform bound) Assume (1.1), (1.2), (1.5), (1.6), (1.7), (1.8), (1.9) and let $u^{\varepsilon}$ be a solution of (1.4). There exists $\varepsilon_{0}>0$ such that

$$
\begin{equation*}
\sup _{0<\varepsilon<\varepsilon_{0}}\left\|u^{\varepsilon}\right\|_{\infty, \Omega}<\infty \tag{3.1}
\end{equation*}
$$

Theorem 3.1, which is very important for the proof of Theorem 1.1, is proved by a blow up argument provided that we can first prove it under the additional assumption that (3.1) holds. The proof of the convergence of the $u^{\varepsilon}$ 's, if (3.1) holds, consists of three steps which we formulate as separate theorems. The first is to show, that along
subsequences, the $u^{\varepsilon}$ 's converge, locally uniformly, in $\Omega \backslash\{0\}$. The next two steps entail the construction of appropriate barriers yielding the convergence away from the origin and, finally, on $\bar{\Omega}$.

We have:
Theorem 3.2. (precompactness) Assume (1.1), (1.2), (1.5), (1.6), (1.7), (1.8), (1.9), and let $u^{\varepsilon}$ be a solution of (1.4) and set $N=\left\{x \in \Omega:\left|D_{0} H(x)\right|>0\right\}$. Let $\left\{\varepsilon_{j}\right\}_{j \in \mathbb{N}} \subset(0, \infty)$ be a sequence converging to zero such that $\sup _{j \in \mathbb{N}}\left\|u^{\varepsilon_{j}}\right\|_{\infty, \Omega}<\infty$. Then the family $\left\{u^{\varepsilon_{j}}\right\}$ is precompact in in $C(N)$.

Theorem 3.3. (outer barriers) Assume (1.1), (1.2), (1.5), (1.6), (1.7), (1.8), (1.9), let $0<h_{0}<\min _{i=1,2,3}\left|h_{i}\right|$ and set $I_{i}=\left(h_{i},-h_{0}\right)$ if $i=1,3$ and $I_{2}=\left(h_{0}, h_{2}\right)$. There exist $\varepsilon_{0} \in(0,1)$ and families $\left\{w_{i}^{\varepsilon}\right\}_{\varepsilon \in\left(0, \varepsilon_{0}\right)} \subset C^{2}\left(\bar{\Omega}_{i} \cap\left\{|H| \geq h_{0}\right\}\right)$, such that $w_{i}^{\varepsilon}$ is a solution of

$$
\begin{gathered}
-\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) w_{i}^{\varepsilon} \leq-1 \quad \text { in } \Omega_{i} \cap\left\{|H|>h_{0}\right\}, \\
w_{i}^{\varepsilon} \leq-1 \quad \text { on } \Omega_{i} \cap\left\{|H|=h_{0}\right\}
\end{gathered}
$$

and, as $\varepsilon \rightarrow 0$, the $w_{i}^{\varepsilon}$ 's converge uniformly to some $w_{i} \in C\left(\bar{\Omega}_{i} \cap\left\{(-1)^{i} H \geq h_{0}\right\}\right)$ and $w_{i}^{\varepsilon} \rightarrow d_{i}$ uniformly on $\partial_{\text {out }} \Omega_{i}$.

Theorem 3.4. (inner barriers) Assume (1.1), (1.2), (1.5), (1.6), (1.7), (1.8) and (1.9). There exist $\varepsilon_{0} \in(0,1)$, a neighborhood $V \subset \Omega$ of the origin and a family $\left\{v^{\varepsilon}\right\}_{\varepsilon \in\left(0, \varepsilon_{0}\right)} \subset C^{2}(V)$ such that $v^{\varepsilon}$ solves

$$
-\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) v^{\varepsilon} \leq-1 \quad \text { in } V
$$

and, as $\varepsilon \rightarrow 0, v^{\varepsilon} \rightarrow 0 \quad$ uniformly on $V$.
Assuming temporarily Theorems 3.1, 3.2, 3.3 and 3.4 , we continue with the
Proof of Theorem 1.1. Theorems 3.1 and 3.2 yield the existence of sequences $\varepsilon_{j} \rightarrow 0$ along which the $u^{\varepsilon_{j}}$ 's converge locally uniformly in $N$.
In order to show the convergence of the whole family $u^{\varepsilon}$ in $\bar{\Omega}$, it is enough to prove that the $u^{\varepsilon_{j}}$ 's converge uniformly in $\bar{\Omega}_{i}$ to $u_{i} \circ H-$ recall that $\left(u_{1}, u_{2}, u_{3}\right)$ is the unique solution of (1.16).

We introduce next the classical half-relaxed limits ( see [2])

$$
u^{+}=\lim \sup ^{*} u^{\varepsilon_{j}} \quad \text { and } \quad u^{-}={\lim \inf _{*} u^{\varepsilon_{j}}}
$$

which, in view Theorem 3.1, are well-defined and bounded on $\bar{\Omega}$. The aim is thus to show that $u^{+}=u^{-}=u_{i} \circ H$ on $\bar{\Omega}_{i}$.

The first step is to prove that, for each $i$, there exists some $v_{i} \in C\left(J_{i}\right)$ such that $u^{+}=u^{-}=v_{i} \circ H$ in $\Omega_{i}$.

Noting that the theory of viscosity solutions yields

$$
-b \cdot D u^{+} \leq 0 \quad \text { and } \quad-b \cdot D u^{-} \geq 0 \quad \text { in } \Omega
$$

it follows that $u^{+}$and $u^{-}$are respectively nondecreasing and nonincreasing along the curve $(X(t, x))_{t \in \mathbb{R}}$, given by (1.11).

Next fix $i \in\{1,2,3\}$ and $x \in \Omega_{i}$ and set $h=H(x)$. The monotonicity of $u^{+}$along the curve $(X(t, x))_{t \in \mathbb{R}}$ yields, for all $t \in\left[0, T_{i}(h)\right]$,

$$
u^{+}(x)=u^{+}\left(X\left(T_{i}(h), x\right)\right) \geq u^{+}(X(t, x)) \geq u^{+}(X(0, x))=u^{+}(x)
$$

i.e., $u^{+}$is constant on the loop $c_{i}(h)$. Similarly, we find that $u^{-}$is constant on the loop $c_{i}(h)$ as well.

Since, in view of (1.8), the loop $c_{i}(h)$ intersects $N$, and, by the choice of the $\varepsilon_{j}$ 's, $u^{+}=u^{-}$in $c_{i}(h) \cap N$ (recall that the $u^{\varepsilon_{j}}$ 's converge in $N$ ), we finally find that, for some constant $v_{i}(h)$ depending on $i$ and $h$,

$$
\begin{equation*}
u^{+}=u^{-}=v_{i}(h) \quad \text { on } \quad c_{i}(h) . \tag{3.2}
\end{equation*}
$$

In particular, $u^{+}=u^{-}$in $\Omega \backslash\{H \neq 0\}$, which implies that $u^{+}=u^{-} \in C(\Omega \backslash\{H \neq$ $0\}$ ), and, hence, $v_{i} \in C\left(J_{i}\right)$.

The next step is to establish that $u^{+}=u^{-}$in $\{H=0\} \backslash\{0\}$. We assume in the rest of proof that (1.10) holds. Then we have that

$$
\begin{gathered}
\{H=0\} \cap S_{\kappa}=\left\{x \in S_{\kappa}: x_{1}=0\right\} \cup\left\{x \in S_{\kappa}: x_{2}=0\right\}, \\
\{H=0\}=c_{2}(0)=c_{1}(0) \cup c_{3}(0),
\end{gathered}
$$

and, for $x \in S_{\kappa} \backslash\{0\}$,

$$
\left|D_{0} H\left(0, x_{2}\right)\right|^{2}=a_{22}\left(0, x_{2}\right) x_{2}^{2} \quad \text { and } \quad\left|D_{0} H\left(x_{1}, 0\right)\right|^{2}=a_{11}\left(x_{1}, 0\right) x_{1}^{2}
$$

In view of (1.9), we may also choose $\kappa>0$ small enough so that $\left|D_{0} H\right|^{2}>0$ in $\{H=0\} \cap S_{\kappa} \backslash\{0\}$. It follows that $\{H=0\} \cap S_{\kappa} \backslash\{0\} \subset N$ and, hence,

$$
u^{+}=u^{-} \quad \text { in } \quad\{H=0\} \cap S_{\kappa} \backslash\{0\} .
$$

Next we fix $i \in\{1,3\}$ and $x \in c_{i}(0) \backslash\{0\}$, and note that there exist $y, z \in c_{i}(0) \cap$ $S_{\kappa}$ and $s<0<t$ such that $X(s, x)=y$ and $X(t, x)=z$. Using, as above, the monotonicity of $u^{ \pm}$along the curves $(X(t, x))_{t \in \mathbb{R}}$, we conclude that $u^{+}=u^{-}=v_{i}(0)$
on $c_{i}(0) \backslash\{0\}$ for some constant $v_{i}(0)$. Moreover, we see that $v_{i}(0)=\lim _{h \rightarrow 0+} u_{i}(h)=$ $\lim _{h \rightarrow 0-} v_{i}(h)$. In particular, setting $v_{2}(0)=\lim _{h \rightarrow 0+} u_{2}(h)$, we find that

$$
v_{1}(0)=v_{2}(0)=v_{3}(0) \text { and } v_{i} \in C\left(J_{i} \cup\{0\}\right)
$$

Now we prove that $u^{+}(0)=u^{-}(0)$. Observe that, in view of Theorem 3.4, there exist $\varepsilon_{0}>0$, a neighborhood $V$ of the origin, and a family $\left\{v^{\varepsilon}\right\}_{\varepsilon \in\left(0, \varepsilon_{0}\right)} \subset C^{2}(V)$ such that

$$
-\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) v^{\varepsilon} \leq-1 \text { in } V \text { and } \lim _{\varepsilon \rightarrow 0}\left\|v^{\varepsilon}\right\|_{\infty, V}=0
$$

By choosing $\kappa>0$ even smaller, if needed, we may assume that $S_{\kappa} \subset V$, and, for $\delta>0$, we set

$$
S_{\kappa, \delta}=\left\{x \in S_{\kappa}:|H(x)| \leq \delta\right\} \quad \text { and } \quad e_{j}(\kappa, \delta)=\max \left\{\left|u^{\varepsilon_{j}}(x)-v_{1}(0)\right|: x \in \partial S_{\kappa, \delta}\right\},
$$

and observe that, since $v_{1}(0)=v_{2}(0)=v_{3}(0)$, for each $i \in\{1,2,3\}$,

$$
\lim _{\delta \rightarrow 0} \lim _{j \rightarrow \infty} e_{j}(\kappa, \delta)=\lim _{\delta \rightarrow 0} \max \left\{\left|v_{i}(h)-v_{i}(0)\right|: 0 \leq(-1)^{i} h \leq \delta\right\}=0
$$

Set

$$
f_{j}=v_{1}(0)-e_{j}(\kappa, \delta)-\left(\|g\|_{\infty, \Omega}+1\right)\left(\left\|v^{\varepsilon_{j}}\right\|_{\infty, V}+v^{\varepsilon_{j}}\right) \quad \text { in } \quad S_{\kappa, \delta},
$$

and note that

$$
\begin{aligned}
& -\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) f_{j} \leq-\|g\|_{\infty, \Omega}-1 \leq g-1 \quad \text { in } \quad S_{\kappa, \delta}, \\
& u^{\varepsilon_{j}} \geq f_{j} \quad \text { on } \partial S_{\kappa, \delta} .
\end{aligned}
$$

The maximum principle implies that $u^{\varepsilon_{j}} \geq f_{j}$ on $S_{\kappa, \delta}$, and, hence, after sending first $j \rightarrow \infty$ and then $\delta \rightarrow 0$, we get $u^{-}(0) \geq v_{1}(0)$.

A similar argument with $f_{j}$ replaced by the function

$$
f_{j}=v_{1}(0)+e_{j}(\kappa, \delta)+\left(\|g\|_{\infty, \Omega}+1\right)\left(\left\|v^{\varepsilon_{j}}\right\|_{\infty, V}-v^{\varepsilon_{j}}\right) \quad \text { for } x \in S_{\kappa, \delta},
$$

yields $u^{+}(0) \leq v_{1}(0)$ and, thus, $u^{+}(0)=u^{-}(0)=v_{i}(0)$ for $i \in\{1,2,3\}$.
Fix $h_{0} \in\left(0, \min _{i=1,2,3}\left|h_{i}\right|\right)$ and observe that, in view of Theorem 3.1, there exist $\varepsilon_{0}, M>0$ so that $M>\|g\|_{\infty, \bar{\Omega}}+\sup _{\varepsilon \in\left(0, \varepsilon_{0}\right)}\left\|u^{\varepsilon}\right\|_{\infty, \Omega}$.

Replacing, if needed, $\varepsilon_{0}$ by a smaller positive number, we recall that Theorem 3.3 yields a family $\left\{w^{\varepsilon}\right\}_{\varepsilon \in\left(0, \varepsilon_{0}\right)} \subset C^{2}\left(\bar{\Omega}_{i} \cap\left\{|H| \geq h_{0}\right\}\right)$ which converges uniformly in $\Omega \cap\left\{|h| \geq h_{0}\right\}$.

In addition,

$$
-\left(\Delta_{0}+\left(b_{0}+\varepsilon^{1} b\right) \cdot D\right) w^{\varepsilon} \leq-1 \quad \text { in } \Omega \cap\left\{|H|>h_{0}\right\} \text { and } w^{\varepsilon} \leq-1 \text { on } \Omega_{i} \cap\left\{|H|=h_{0}\right\}
$$

## A PDE APPROACH TO SMALL STOCHASTIC PERTURBATIONS OF HAMILTONIAN FLOWSI 7

 and$$
\lim _{\varepsilon \rightarrow 0} w^{\varepsilon}=M^{-1} d_{i} \quad \text { on } \quad \partial_{\text {out }} \Omega_{i} .
$$

If

$$
f^{\varepsilon}=M w^{\varepsilon}-\max \left\{\left|\rho^{\varepsilon}(x)-d_{i}\right|: x \in \partial_{\text {out }} \Omega_{i}, i=1,2,3\right\},
$$

then

$$
-\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) f^{\varepsilon} \leq-M<g \quad \text { in } \Omega \cap\left\{|H|>h_{0}\right\},
$$

$$
f^{\varepsilon} \leq u^{\varepsilon} \quad \text { on } \partial\left(\Omega \cap\left\{|H|>h_{0}\right\}\right) \quad \text { and } \quad \lim _{\varepsilon \rightarrow 0} f^{\varepsilon}=d_{i} \quad \text { uniformly on } \partial_{\text {out }} \Omega_{i} \text {. }
$$

Since, by comparison, $f^{\varepsilon} \leq u^{\varepsilon}$ on $\bar{\Omega} \cap\left\{|H|>h_{0}\right\}$, for each $i \in\{1,2,3\}$, we find that $d_{i} \leq u^{-}$on $\partial_{\text {out }} \Omega_{i}$, and, by a similar argument, $d_{i} \geq u^{+}$on $\partial_{\text {out }} \Omega_{i}$. Hence, $u^{-}=u^{+}=d_{i}$ on $\partial_{\text {out }} \Omega_{i}$.

Since $u^{+}=u^{-}$everywhere, it is now easy to see that, as $j \rightarrow \infty$,

$$
u^{\varepsilon_{j}} \rightarrow v_{i} \circ H \quad \text { uniformly on } \bar{\Omega}_{i} \text {. }
$$

The last step is to identify $\left(v_{1}, v_{2}, v_{3}\right)$ as the unique solution of (1.16), and, hence, conclude that, as $\varepsilon \rightarrow 0$, the $u^{\varepsilon}$ 's converge to $u_{i} \circ H$ uniformly in $\bar{\Omega}$.

To this end, fix $i \in\{1,2,3\}$ and $\phi \in C_{0}^{2}\left(J_{i}\right)$. Integrating (1.4) by parts, we find

$$
\int_{\Omega_{i}}\left\{u^{\varepsilon}\left(\phi^{\prime \prime} \circ H\left|D_{0} H\right|^{2}+\phi^{\prime} \circ H\left(\Delta_{0} H-b_{0} \cdot D H\right)-\operatorname{div} b_{0} \phi \circ H\right)+g \phi \circ H\right\} d x=0 .
$$

Taking $\varepsilon=\varepsilon_{j}$ and sending $j \rightarrow \infty$, we get

$$
\begin{equation*}
\int_{J_{i}} T_{i}(h)\left\{\left(A_{i} v_{i} \phi^{\prime \prime}+\left(B_{i}-B_{0 i}\right) v_{i} \phi^{\prime}\right)+\left(\hat{g}_{i}-C_{0 i} v_{i}\right) \phi\right\} d h=0 . \tag{3.3}
\end{equation*}
$$

Since $\phi$ is arbitrary, in view of (2.3), (2.5) and (2.6), (3.3) gives

$$
A_{i} v_{i}^{\prime \prime}+\left(B_{i}+B_{0 i}\right) v_{i}^{\prime}+\hat{g}_{i}=0 \quad \text { in } \quad J_{i} .
$$

Next fix $\phi \in C_{0}^{2}(J)$ with $J=\left(\max \left\{h_{1}, h_{3}\right\}, h_{2}\right)$, and observe, as above, that

$$
\int_{\Omega}\left\{u^{\varepsilon}\left(\phi^{\prime \prime} \circ H\left|D_{0} H\right|^{2}+\phi^{\prime} \circ H\left(\Delta_{0} H-b_{0} \cdot D H\right)-\operatorname{div} b_{0} \phi \circ H\right)+g \phi \circ H\right\} d x=0,
$$

and, therefore,

$$
\begin{align*}
0= & \int_{0}^{h_{2}} T_{2}\left\{\left(A_{2} v_{2} \phi^{\prime \prime}+\left(B_{2}-B_{02}\right) v_{2} \phi^{\prime}\right)+\left(\hat{g}_{2}-C_{02} v_{2}\right) \phi\right\} d h \\
& +\sum_{i=1,3} \int_{h_{i}}^{0} T_{i}\left\{\left(A_{i} v_{i} \phi^{\prime \prime}+\left(B_{i}-B_{0 i}\right) v_{i} \phi^{\prime}\right)+\left(\hat{g}_{i}-C_{0 i} v_{i}\right) \phi\right\} d h . \tag{3.4}
\end{align*}
$$

Since

$$
\left(T_{i} A_{i} v_{i} \phi^{\prime}-T_{i} A_{i} v_{i}^{\prime} \phi\right)^{\prime}=\left(T_{i} A_{i}\right)^{\prime} v_{i} \phi^{\prime}+T_{i} A_{i} \phi^{\prime \prime}-\left(T_{i} A_{i} v_{i}^{\prime}\right)^{\prime} \phi,
$$

and

$$
\left(T_{i} B_{0 i} v_{i} \phi\right)^{\prime}=T_{i} B_{0 i} v_{i} \phi^{\prime}+\left(T_{i} B_{0 i}\right)^{\prime} v_{i} \phi+T_{i} B_{0 i} v_{i}^{\prime} \phi
$$

integrating by parts, with $0<\delta<h_{2}$, and using (2.4) and (2.5) we find

$$
\begin{aligned}
- & \left(T_{2} A_{2} v_{2} \phi^{\prime}-T_{2} A_{2} v_{2}^{\prime} \phi-T_{2} B_{02} v_{2} \phi\right)(\delta) \\
= & \int_{\delta}^{h_{2}}\left\{\left(T_{2} A_{2}\right)^{\prime} v_{2} \phi^{\prime}+T_{2} A_{2} \phi^{\prime \prime}-\left(T_{2} A_{2} v_{2}^{\prime}\right)^{\prime} \phi-\left(T_{2} B_{02} v_{2} \phi^{\prime}+\left(T_{2} B_{02}\right)^{\prime} v_{2} \phi\right)\right. \\
& \left.+T_{2} B_{02} v_{2}^{\prime} \phi\right\} d h \\
= & \int_{\delta}^{h_{2}}\left\{T_{2} A_{2} \phi^{\prime \prime}+T_{2} B_{2} v_{2} \phi^{\prime}-\left(T_{2} B_{02} v_{2} \phi^{\prime}+T_{2} C_{02} v_{2} \phi\right)-\left(T_{2} A_{2} v_{2}^{\prime}\right)^{\prime} \phi-T_{2} B_{02} v_{2}^{\prime} \phi\right\} d h \\
= & \int_{\delta}^{h_{2}}\left\{T_{2} A_{2} \phi^{\prime \prime}+T_{2} B_{2} v_{2} \phi^{\prime}-\left(T_{2} B_{02} v_{2} \phi^{\prime}+T_{2} C_{02} v_{2} \phi\right)-\left(T_{2} A_{2} v_{2}^{\prime}\right)^{\prime} \phi-T_{2} B_{02} v_{2}^{\prime} \phi\right\} d h \\
= & \int_{\delta}^{h_{2}}\left\{T_{2} A_{2} \phi^{\prime \prime}+T_{2} B_{2} v_{2} \phi^{\prime}-\left(T_{2} B_{02} v_{2} \phi^{\prime}+T_{2} C_{02} v_{2} \phi\right)+T_{2} \hat{g}_{2} \phi\right\} d h .
\end{aligned}
$$

Hence,

$$
\begin{aligned}
& -\left(T_{2} A_{2} v_{2} \phi^{\prime}-T_{2} A_{2} v_{2}^{\prime} \phi-T_{2} B_{02} v_{2} \phi\right)(0) \\
& =\int_{0}^{h_{2}}\left\{T_{2} A_{2} \phi^{\prime \prime}+T_{2} B_{2} v_{2} \phi^{\prime}-\left(T_{2} B_{02} v_{2} \phi^{\prime}+T_{2} C_{02} v_{2} \phi\right)+T_{2} \hat{g}_{2} \phi\right\} d h .
\end{aligned}
$$

Similarly, for $i \in\{1,3\}$, we have

$$
\begin{aligned}
& \left(T_{i} A_{i} v_{i} \phi^{\prime}-T_{i} A_{i} v_{i}^{\prime} \phi-T_{i} B_{0 i} v_{i} \phi\right)(0) \\
= & \int_{h_{i}}^{0}\left\{T_{i} A_{i} \phi^{\prime \prime}+T_{i} B_{i} v_{i} \phi^{\prime}-\left(T_{i} B_{0 i} v_{i} \phi^{\prime}+T_{i} C_{0 i} v_{i} \phi\right)+T_{i} \hat{g}_{i} \phi\right\} d h,
\end{aligned}
$$

and, therefore, in view of (3.4) and (2.8),
$0=\left(-\beta_{2} v_{2}(0)+\sum_{i=1,3} \beta_{i} v_{i}(0)\right) \phi^{\prime}(0)+\left(\beta_{2} v_{2}^{\prime}(0)+\gamma_{2} v_{2}(0)-\sum_{i=1,3}\left(\beta_{i} v_{i}^{\prime}(0)+\gamma_{i} v_{i}(0)\right)\right) \phi(0)$.
If we choose $\phi$ so that $\phi^{\prime}(0)=0$ and $\phi(0) \neq 0$ and note that $\gamma_{2}=\sum_{i=1,3} \gamma_{i}$, by Lemma 2.5, and $v_{1}(0)=v_{2}(0)=v_{3}(0)$, then we find that the boundary condition

$$
\begin{equation*}
\beta_{2} v_{2}^{\prime}(0)=\sum_{i=1,3} \beta_{i} v_{i}^{\prime}(0) \tag{3.5}
\end{equation*}
$$

is satisfied. Thus the triple $\left(v_{1}, v_{2}, v_{3}\right)$ is the solution of (1.16).
We conclude this Section with the

Proof of Theorem 3.1. We use a standard blow-up argument. Arguing by contradiction, we assume that there exists $\varepsilon_{j} \rightarrow 0$ such that

$$
\lim _{j \rightarrow \infty}\left\|u^{\varepsilon_{j}}\right\|_{\infty, \Omega}=\infty
$$

To this end, let $M_{j}=\left\|u^{\varepsilon_{j}}\right\|_{\infty, \Omega}, \phi_{j}=u^{\varepsilon_{j}} / M_{j}$, and observe that $\phi_{j}$ is a solution of (1.4), with $\varepsilon, g$ and $\rho^{\varepsilon}$ replaced respectively by $\varepsilon_{j}, g / M_{j}$ and $\rho^{\varepsilon_{j}} / M_{j}$. Moreover, as $j \rightarrow \infty$, the $g / M_{j}$ 's and $\rho^{\varepsilon_{j}} / M_{j}$ 's converge to zero uniformly on $\Omega$ and $\partial \Omega$ respectively. Finally, we have $\left\|\phi_{j}\right\|_{\infty, \Omega}=1$ for $j \in \mathbb{N}$.

We may now apply the argument of the proof of Theorem 1.1, where the uniform boundedness of the $u^{\varepsilon}$ s is assumed, to the sequence $\left\{\phi_{j}\right\}$ in place of $\left\{u^{\varepsilon_{j}}\right\}$ to conclude that the $\phi_{j}$ 's converge uniformly in $\bar{\Omega}$ to $\psi_{i} \circ H$ on $\bar{\Omega}_{i}$, where the triple $\left(\psi_{1}, \psi_{2}, \psi_{3}\right)$ is the unique solution of (1.16) with $d_{i}=0$ for all $i$. Obviously, the triple $(0,0,0)$ is a solution of this ode problem. Therefore, we have $\psi_{i}=0$ for all $i$. However, this shows that the functions $\phi_{j}$ converge to zero uniformly on $\Omega$ as $j \rightarrow \infty$, which contradicts the fact that $\left\|\phi_{j}\right\|_{\infty, \Omega}=1$ for all $j$.

## 4. The local compactness

To prove Theorem 3.2 it is necessary to obtain some, independent of $\varepsilon$, apriori bounds for $D u^{\varepsilon}$. Since the matrix $A$ may be degenerate, we do not have global Lipschitz bounds for the $u^{\varepsilon}$ 's. To go around this difficulty, we use the structure of the Hamiltonian $H$. In particular we use the fact that, if for some unit vector $e \in \mathbb{R}^{2}$ and $x \in \Omega, e \cdot D H(x) \neq 0$, then, in a neighborhood of $x$, (1.4) behaves like a parabolic equation, with $-b$ as the time direction, and a small parameter in front of the all the other terms.

In the next Theorem, we assume some apriori bounds, which we prove later, and show the existence of a convergent subsequence $u^{j}=u^{\varepsilon_{j}}$ as $\varepsilon_{j} \rightarrow 0$.

Theorem 4.1. Fix $x_{0} \in \Omega$ and a sequence $\varepsilon_{j} \rightarrow 0$, and, in addition to the assumptions of Theorem 3.2, assume that, for some unit vector $e_{0} \in \mathbb{R}^{2}$ and a compact neighborhood $U \subset \Omega$ of $x_{0}, e_{0} \cdot D H\left(x_{0}\right) \neq 0$ and

$$
\begin{equation*}
\sup _{j \in \mathbb{N}}\left(\left\|u^{\varepsilon_{j}}\right\|_{\infty, U}+\int_{U}\left(e_{0} \cdot D u^{\varepsilon_{j}}(x)\right)^{2} d x\right)<\infty \tag{4.1}
\end{equation*}
$$

There exists a neighborhood $V$ of $x_{0}$ and a subsequence $\left\{u^{\varepsilon_{j_{k}}}\right\}_{k \in \mathbb{N}}$ such that

$$
\limsup _{k \rightarrow \infty}^{*} u^{\varepsilon_{j_{k}}}=\liminf _{k \rightarrow \infty} u^{\varepsilon_{j_{k}}} \text { in } V
$$

Proof. After rotating coordinates (see Appendix) we may assume that $e_{0}=(0,1)$ and, hence, $e_{0} \cdot D H(x)=H_{x_{2}}(x)$. Moreover to simplify the presentation we write $u^{j}$ for $u^{\varepsilon_{j}}$.

First we prove the claim in the special case that, for all $x \in U, H(x)=x_{2}$ where, for $a, b>0, U=\left[x_{01}-a, x_{01}+a\right] \times\left[x_{02}-b, x_{02}+b\right]$.

To this end, we write $(s, t)$ for $x-x_{0}$, i.e., $x_{1}=x_{01}+s$ and $x_{2}=x_{02}+t$, and, thus, we regard $u^{j}, a_{i j}, b_{0}$ and $g$ as functions of $(s, t)$, and we note that, in this simplified setting, $\bar{D} H(x)=(1,0)$ for $x \in U$ and the pde for $u=u^{j}$ in $U$ is the parabolic-like equation

$$
-\Delta_{0} u-b_{0} \cdot D u-\varepsilon_{j}^{-1} u_{s}=g .
$$

Since, by assumption, there exists $C>0$ such that, for all $j \in \mathbb{N}$,

$$
\left\|u^{j}\right\|_{\infty, U}+\int_{U} u_{t}^{j^{2}} d s d t \leq C
$$

Chebychev's inequality yields

$$
\min _{a / 2 \leq s \leq a} \int_{-b}^{b} u_{t}^{j}(s, t)^{2} d t \leq \frac{2 C}{a}
$$

and, for each $j \in \mathbb{N}$, we may choose $s_{j} \in[a / 2, a]$ so that

$$
\int_{-b}^{b} u_{t}^{j}\left(s_{j}, t\right)^{2} d t \leq \frac{C}{a}
$$

Set, for $r \geq 0, \omega(r)=(C r / a)^{1 / 2}$, and observe that, for all $t_{1}, t_{2} \in[-b, b]$ and $j \in \mathbb{N}$,

$$
\begin{equation*}
\left|u^{j}\left(s_{j}, t_{1}\right)-u^{j}\left(s_{j}, t_{2}\right)\right| \leq \omega\left(\left|t_{1}-t_{2}\right|\right) \tag{4.2}
\end{equation*}
$$

It follows from the Ascoli-Arzela theorem that there exist $\phi \in C([-b, b])$ and a sequence $j_{k} \rightarrow \infty$ such that, as $k \rightarrow \infty$ and on $[-b, b]$,

$$
u^{j_{k}}\left(s_{j}, \cdot\right) \rightarrow \phi(\cdot) .
$$

Fix $\gamma>0$, choose $\rho \in(0, b / 3)$ so that $\omega(2 \rho)<\gamma, p, q \in C^{2}(\mathbb{R} ;[0, \infty))$ such that

$$
\begin{gathered}
p=0 \quad \text { in }[-\rho, \rho] \text { and } p \geq 2 C \text { in } \mathbb{R} \backslash(-2 \rho, 2 \rho), \\
q^{\prime} \leq 0 \quad \text { in } \mathbb{R}, q=0 \quad \text { in }[-a / 2, \infty) \text { and } q(-a) \geq 2 C,
\end{gathered}
$$

and note that, for any $\tau \in[-b / 3, b / 3],(-a, a) \times(\tau-2 \rho, \tau+2 \rho) \subset U$.
Finally fix $\tau \in[-b / 3, b / 3]$ and $j \in \mathbb{N}$, let $W=\left(-a, s_{j}\right) \times(\tau-2 \rho, \tau+2 \rho)$, and, for $(s, t) \in \bar{W}$, set

$$
w(s, t)=u^{j}\left(s_{j}, \tau\right)+\gamma+p(t-\tau)+\gamma\left(s_{j}-s\right)+q(s)
$$

We note that in the remainder of the proof the claims we are making are valid for sufficiently large $j$.

It follows that, on $\bar{W}$,

$$
-w_{s}-\varepsilon_{j}\left(\Delta_{0} w+b_{0} \cdot D w+g\right) \geq \gamma-\varepsilon_{j}\left(\Delta_{0} w+b_{0} \cdot D w+g\right)>0
$$

and thus, if $w \geq u^{j}$ on $\partial W$, the maximum principle yields

$$
w \geq u^{j} \quad \text { on } \quad W .
$$

For the comparison on $\partial W$, observe that, if $|t-\tau|=2 \rho$, then

$$
\begin{gathered}
w(s, t) \geq u^{j}\left(s_{j}, \tau\right)+2 C \geq C \geq u^{j}\left(s_{j}, t\right), \\
w(-a, t) \geq u^{j}\left(s_{j}, t\right)+q(-a) \geq C \geq u^{j}(-a, t),
\end{gathered}
$$

and, since $|t-\tau| \leq 2 \rho$,

$$
w\left(s_{j}, t\right) \geq u^{j}\left(s_{j}, \tau\right)+\gamma \geq u\left(s_{j}, \tau\right)+\omega(2 \rho) \geq u^{j}\left(s_{j}, t\right)
$$

Similarly, for $(s, t) \in\left(-a, s_{j}\right) \times(\tau-2 \rho, \tau+2 \rho)$, we get

$$
u^{j}(s, t) \geq u^{j}\left(s_{j}, \tau\right)-\gamma-p(t-\tau)-\gamma\left(s_{j}-s\right)-q(s) .
$$

In particular, if $(s, t) \in(-a / 2, a / 2) \times(\tau-\rho, \tau+\rho)$, we have

$$
\left|u^{j}(s, t)-u^{j}\left(s_{j}, \tau\right)\right| \leq \gamma\left(1+s_{j}-s\right) \leq \gamma(1+2 a)
$$

Hence, since $\lim _{j \rightarrow \infty} u^{j}\left(s_{j}, \tau\right)=\phi(\tau)$, for $s \in(-a / 2, a / 2)$, we obtain

$$
\limsup _{k \rightarrow \infty}^{*} u^{j_{k}}(s, \tau) \leq \phi(\tau)+2 \gamma(1+a)
$$

and

$$
\liminf _{k \rightarrow \infty} u^{j_{k}}(s, \tau) \geq \phi(\tau)-2 \gamma(1+a)
$$

Finally, since $\gamma>0$ and $\tau \in(-b / 3, b / 3)$ are arbitrary, we conclude that

$$
\limsup _{k \rightarrow \infty}^{*} u^{j_{k}}=\liminf _{k \rightarrow \infty} u^{j_{k}}=\phi \quad \text { on }(-a / 2, a / 2) \times(-b / 3, b / 3),
$$

and the proof of the claim in this simplified setting is complete.
Next, we show that it is possible, after a change of variables, to transform the general setting into the one studied above.

To this end, let $\Phi: U \rightarrow \mathbb{R}^{2}$ be given by $\Phi(x)=\left(x_{1}, H(x)\right)$. Since $H_{x_{2}}\left(x_{0}\right)>0, \Phi$ is an order-preserving diffeomorphism from a neighborhood of $x_{0}$ to a neighborhood of $\left(x_{01}, H\left(x_{0}\right)\right)$. Setting $v^{j}(\Phi(x))=u^{j}(x)$ and $\widetilde{H}(\Phi(x))=H(x)$, in the new variable $y=\Phi(x)$, we have

$$
\widetilde{H}(y)=y_{2} \quad \text { and } \quad \bar{D} \widetilde{H}(y)=(1,0) .
$$

Consequently, in view of invariance of the form of the pde (1.4) under change of variables (see Appendix), we deduce that $v^{j}$ satisfies, in a neighborhood of $\left(x_{01}, H\left(x_{0}\right)\right)$ and for some $\tilde{b}_{0}$ and $\tilde{g}$,

$$
-\tilde{\Delta}_{0} v^{j}-\tilde{b}_{0} \cdot D v^{j}-\varepsilon_{j}^{-1} v_{y_{1}}^{j}=\tilde{g},
$$

where $\widetilde{\Delta}_{0} w=\left(\tilde{a}_{11} w_{y_{1}}+\tilde{a}_{12} w_{y_{2}}\right)_{y_{1}}+\left(\tilde{a}_{21} w_{y_{1}}+\tilde{a}_{22} w_{y_{2}}\right)_{y_{2}}$ for some $\tilde{a}_{i j}$.
Also, noting that $u_{x_{2}}^{j}(x)=v_{y_{2}}^{j}(\Phi(x)) H_{x_{2}}(x)$ and $\operatorname{det} D \Phi(x)=H_{x_{2}}(x)$, we find that, in a small neighborhood $\widetilde{U}$ of $\left(x_{01}, H\left(x_{0}\right)\right)$,

$$
\sup _{j \in \mathbb{N}}\left(\left\|v^{j}\right\|_{\infty, \tilde{U}}+\int_{\widetilde{U}} v_{y_{2}}^{j}(y)^{2} d y\right)<\infty
$$

The proof is now complete.
We proceed with the proofs of the (4.1) and, in particular, the integral bound since the sup-estimate follows from Theorem 3.1. Throughout the arguments below we assume that Theorem 3.4 holds. Its proof will be presented in Section 6.

We have:
Lemma 4.1. Let $u^{\varepsilon}$ be a solution of (1.4). For any compact subset $K$ of $\Omega$, there exists a constant $C_{K}>0$ such that for all $0<\varepsilon<1$,

$$
\int_{K}\left|D_{0} u^{\varepsilon}\right|^{2} d x \leq C_{K}\left(\left\|u^{\varepsilon}\right\|_{\infty, \Omega}^{2}+1\right)
$$

Proof. Fix $\varepsilon \in\left(0, \varepsilon_{0}\right)$ and let $\phi \in C_{0}^{2}\left(J_{i}\right)$. Then

$$
\int_{\Omega_{i}}\left\{\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) u^{\varepsilon}+g\right\} \phi \circ H d x=0
$$

In addition,

$$
\begin{aligned}
\int_{\Omega_{i}} \Delta_{0} u^{\varepsilon} u^{\varepsilon} \phi \circ H d x & =-\int_{\Omega_{i}}\left(\left|D_{0} u^{\varepsilon}\right|^{2} \phi \circ H+\phi^{\prime} \circ H\left\langle D u^{\varepsilon}, D h\right\rangle_{0}\right) d x \\
& \geq-\int_{\Omega_{i}}\left(\left|D_{0} u^{\varepsilon}\right|^{2} \phi \circ H-\left|D_{0} u^{\varepsilon}\right|\left|D_{0} H\right| \phi^{\prime} \circ H\right) d x
\end{aligned}
$$

where, for $x \in \Omega$ and $\xi, \eta \in \mathbb{R}^{2}$,

$$
\langle\xi, \eta\rangle_{0}=a_{11}(x) \xi_{1} \eta_{1}+a_{12}(x)\left(\xi_{1} \eta_{2}+\xi_{2} \eta_{1}\right)+a_{22}(x) \xi_{2} \eta_{2}
$$

Moreover,

$$
2 \int_{\Omega_{i}}\left(b_{0} \cdot D u^{\varepsilon}\right) u^{\varepsilon} \phi \circ H d x=\int_{\Omega_{i}}\left(\phi \circ H b_{0}\right) \cdot D\left(u^{\varepsilon}\right)^{2} d x=-\int_{\Omega_{i}}\left(u^{\varepsilon}\right)^{2} \operatorname{div}\left(\phi \circ H b_{0}\right) d x,
$$

and
$2 \int_{\Omega_{i}}\left(b \cdot D u^{\varepsilon}\right) u^{\varepsilon} \phi \circ H d x=-\int_{\Omega_{i}}\left(u^{\varepsilon}\right)^{2} \operatorname{div}(\phi \circ H b) d x=-\int_{\Omega_{i}}\left(u^{\varepsilon}\right)^{2} \phi^{\prime} \circ H b \cdot D H d x=0$.
Replacing $\phi$ by $\phi^{2}$ in the above computation and recalling Theorem 3.1, we find $C>0$, depending only on $\sup _{0<\varepsilon<\varepsilon_{0}}\left\|u^{\varepsilon}\right\|_{\infty, \Omega}, H, \phi, a_{i j}$ and $b_{0}$ such that

$$
\begin{equation*}
\int_{\Omega_{i}}\left|D_{0} u^{\varepsilon}\right|^{2} \phi^{2} \circ H d x \leq C\left(\left\|u^{\varepsilon}\right\|_{\infty, \Omega}^{2}+1\right) \tag{4.3}
\end{equation*}
$$

Similarly, if $\phi \in C_{0}^{2}(J)$ with $J=\left(\max _{i=1,3} h_{i}, h_{2}\right)$, then, for some $C>0$, we also have

$$
\begin{equation*}
\int_{\Omega}\left|D_{0} u^{\varepsilon}\right|^{2} \phi^{2} \circ H d x \leq C\left(\left\|u^{\varepsilon}\right\|_{\infty, \Omega}^{2}+1\right) \tag{4.4}
\end{equation*}
$$

Combining (4.3) and (4.4) yields the claim.
We present now the
Proof of Theorem 3.2. The precompactness of the family $\left\{u^{\varepsilon}\right\}_{\varepsilon>0}$ in $C(N)$ follows from standard compactness and diagonal arguments once we show that, for each $x_{0} \in N$ and every sequence $\varepsilon_{j} \rightarrow 0$, there exists a subsequence $\varepsilon_{j_{k}} \rightarrow 0$ and a neighborhood $V$ of $x_{0}$ such that, if $u^{k}=u^{\varepsilon_{j}}$,

$$
\underset{k \rightarrow \infty}{\limsup ^{*}} u^{k}=\liminf _{k \rightarrow \infty} u^{k} \text { in } V .
$$

To prove the claim we use Theorem 4.1. Thus we only need to find a vector $e_{0} \in \mathbb{R}^{2}$ for which (4.1) holds. This will be done again using a convenient change of variables.

To simplify the notation, for the rest of the proof, we write $\alpha=a_{11}, \beta=a_{12}=a_{21}$ and $\gamma=a_{22}$ suppressing, unless necessary, the explicit $x$-dependence, and, after some relabeling, we assume that $j=1$.

Fix a compact neighborhood $U \subset \Omega$ of $x_{0}$. It follows from Theorem 3.1 and Lemma 4.1, that, for $\tilde{j} \in \mathbb{N}$ large enough,

$$
\sup _{j \geq \tilde{j}}\left(\left\|u^{j}\right\|_{\infty, U}+\int_{U}\left|D_{0} u^{j}\right|^{2} d x\right)<\infty .
$$

Since $A D H \cdot D H\left(x_{0}\right)>0$, we have either $(\alpha, \beta) \cdot D H\left(x_{0}\right) \neq 0$ or $(\beta, \gamma) \cdot D H\left(x_{0}\right) \neq 0$, since, otherwise, $A D H\left(x_{0}\right)=0$. Next we assume $(\beta, \gamma) \cdot D H\left(x_{0}\right) \neq 0$. The other case can be treated in a similar way.

Set $e=(\beta, \gamma)$ on $\Omega$. By replacing, if needed, $U$ by a smaller neighborhood, we may assume that $e \cdot D H \neq 0$ in $U$. The degenerate ellipticity of $\Delta_{0}$ yields $\alpha \gamma \geq \beta^{2}$ in $\Omega$ and, therefore, we must have $\gamma>0$ in $U$.

Observe that, for any $y=\left(y_{1}, y_{2}\right) \in \mathbb{R}^{2}, x \in U$ and $C_{\gamma}=\max _{U} \gamma$,

$$
\begin{aligned}
(e(x) \cdot y)^{2} & =\beta^{2}(x) y_{1}^{2}+2 \beta(x) \gamma(x) y_{1} y_{2}+\gamma^{2}(x) y_{2}^{2} \\
& \leq \alpha(x) \gamma(x) y_{1}^{2}+2 \beta(x) \gamma(x) y_{1} y_{2}+\gamma^{2}(x) y_{2}^{2}=\gamma(x) A(x) y \cdot y \leq C_{\gamma} A(x) y \cdot y .
\end{aligned}
$$

Hence,

$$
\int_{U}\left(e(x) \cdot D u^{j}(x)\right)^{2} d x \leq C_{\gamma}^{2} \int_{U}\left|D_{0} u^{j}\right|^{2} d x .
$$

Next we change variables to "straighten" the vector field $e$. To do this end, let $X(s, t)$ be the solution the initial value problem

$$
\frac{\partial X(s, t)}{\partial t}=e(X(s, t)) \quad \text { with } \quad X(s, 0)=x_{0}+(s, 0)
$$

and recall that $X(s, t)$ is smooth in a neighborhood $W$ of the origin $(s, t)=(0,0)$.
Note that, since

$$
D X=\left(\begin{array}{ll}
X_{1, s} & \beta(X) \\
X_{2, s} & \gamma(X)
\end{array}\right)
$$

where $X=\left(X_{1}, X_{2}\right)$ and $X_{1, s}(s, 0)=1$, it follows that $\operatorname{det} D X(0,0)=\gamma\left(x_{0}\right)>0$. Thus, by reselecting, if necessary, $W$ small enough and setting $U=X(W)$, since $\gamma\left(x_{0}\right)>0$, we may assume that $X: W \rightarrow U$ is an orientation-preserving diffeomorphism.

Let $x=X(y)$. Setting $v^{j}(y)=u^{j}(X(y))$ and $e_{2}=(0,1) \in \mathbb{R}^{2}$ and noting that $D X(y) e_{2}=e(X(y))$, we get, for $C_{X}=1 / \min _{W}|\operatorname{det} X|$,

$$
\begin{aligned}
\int_{W}\left(e_{2} \cdot D v^{j}(y)\right)^{2} d y & =\int_{W}\left(e_{2} \cdot D X(y)^{*} D u^{j}(X(y))\right)^{2} d y \\
& \leq C_{X} \int_{W}\left(D X(y) e_{2} \cdot D u(X(y))^{2}|\operatorname{det} X(y)| d y\right. \\
& \leq C_{X} \int_{W}\left(e \cdot D u^{j}\right)^{2} \circ X d x
\end{aligned}
$$

where $D X(y)^{*}$ denotes the transposed matrix of $D X(y)$.
It follows that (4.1) holds with $e_{0}=e_{2}$ in the new coordinate system. Similarly, if we set $\widetilde{H}=H \circ X$, then

$$
e_{2} \cdot D \widetilde{H}(y)=e_{2} \cdot D X(y)^{*} D H \circ X=e \cdot D H \circ X \neq 0 .
$$

Applying Theorem 4.1 we conclude the proof.

## A PDE APPROACH TO SMALL STOCHASTIC PERTURBATIONS OF HAMILTONIAN FLOWS25

## 5. The construction of the barriers

The key step of the proof of Theorem 3.3 is
Theorem 5.1. Let $h_{0}$ and $I_{i}$ be as in Theorem 3.3, set $W_{i}=\Omega_{i} \cap\left\{|H|>h_{0}\right\}$, and assume that $w_{i} \in C^{4}\left(I_{i}\right)$ satisfy

$$
-\left(A_{i} w_{i}^{\prime \prime}+\left(B_{i}+B_{0 i}\right) w_{i}^{\prime}\right)+2 \leq 0 \quad \text { in } I_{i} .
$$

There exist $\zeta_{i}^{\varepsilon} \in C^{2}\left(\bar{W}_{i}\right)$ and $\varepsilon_{0}>0$ such that, if $\varepsilon \in\left(0, \varepsilon_{0}\right)$, then

$$
-\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) \zeta_{i}^{\varepsilon}+1 \leq 0 \quad \text { in } W_{i} \quad \text { and } \lim _{\varepsilon \rightarrow 0}\left\|w_{i}-\zeta_{i}^{\varepsilon}\right\|_{\infty, W_{i}}=0
$$

Before going into the proof of Theorem 5.1, we need to introduce some auxiliary functions. To this end, recall that $l_{1}$ and $l_{3}$ are respectively the curves $\left\{Y_{1}(h): h_{1} \leq\right.$ $\left.h \leq h_{2}\right\}$ and $\left\{Y_{3}(h): h_{3} \leq h \leq h_{2}\right\}$, while $l_{2}$ is either of $l_{1}$ and $l_{3}$. Then for each $x \in V_{i}=\Omega_{i} \cup \partial_{\text {out }} \Omega_{i}, \tau_{i}(x)$ is the first time the flow $(X(t, x))_{t>0}$ hits the curve $l_{i}$, i.e.,

$$
X\left(\tau_{i}(x), x\right) \in l_{i}, \quad \text { and } \quad X(t, x) \notin l_{i} \quad \text { for all } \quad t \in\left(0, \tau_{i}(x)\right)
$$

It follows that $\tau_{i}=T_{i} \circ H$ in $l_{i} \cap V_{i}$ and $\tau_{i} \leq T_{i} \circ H$ in $V_{i}$. Also note that, although $\tau_{i}$ is continuous in $V_{i} \backslash l_{i}$, it is not, in general, continuous across $l_{i}$. To go around this difficulty, we modify the $\tau_{i}$ 's near $l_{i}$ by considering the neighborhoods $U_{i}=\left\{x \in V_{i}: \tau_{i}(x) \neq T_{i}(H(x)) / 2\right\}$ and the continuous maps $\tilde{\tau}_{i}: U_{i} \rightarrow(0, \infty)$ defined by

$$
\tilde{\tau}_{i}(x)=\left\{\begin{array}{lll}
\tau_{i}(x) & \text { if } & \tau_{i}(x)>T_{i}(H(x)) / 2 \\
\tau_{i}(x)+T_{i}(H(x)) & \text { if } & \tau_{i}(x)<T_{i}(H(x)) / 2
\end{array}\right.
$$

When we discuss the regularity of the $\tau_{i}$ 's near $l_{i} \cap V_{i}$, we implicity refer to the $\tilde{\tau}_{i}$ 's.
We have:
Lemma 5.1. $\tau_{i} \in C^{3}\left(V_{i}\right)$.
Proof. As it has been already noted in the proof of Lemma 2.1, there exists $\phi \in$ $C^{3}\left(\mathbb{R}^{2} ; \mathbb{R}\right)$ such that $\phi=0$ and $D \phi \neq 0$ on $l_{i}$. Set $\psi(t, x)=\phi(X(t, x))$. Since $\psi\left(\tau_{i}(x), x\right)=0$ for $x \in V_{i}$ and $\psi_{t}\left(\tau_{i}(x), x\right)=D \phi\left(Y_{i}(H(x))\right) \cdot b\left(Y_{i}(H(x))\right) \neq 0$ for $x \in V_{i}$, the implicit function theorem yields that $\tau_{i}$ is locally (in the sense that it has to be replaced by $\tilde{\tau}_{i}$ near $l_{i}$ ) of class $C^{3}$.

We continue with the
Proof of Theorem 5.1. We only show the existence of $\zeta_{2}^{\varepsilon}$, since the construction of $\zeta_{1}^{\varepsilon}$ and $\zeta_{2}^{\varepsilon}$ is similar.

To this end, recall that $X, \dot{X} \in C^{2}\left(\mathbb{R} \times \bar{W}_{2}\right), \tau \in C^{2}\left(\bar{W}_{2}\right), T_{2} \in C^{2}\left(\bar{I}_{2}\right), A_{2}, B_{2} \in$ $C^{2}\left(\bar{I}_{2}\right), w_{2} \in C^{4}\left(\bar{I}_{2}\right)$, set

$$
f=\left(\Delta_{0}+b_{0} \cdot D\right)\left(w_{2} \circ H\right)-\left(A_{2} w_{2}^{\prime \prime} \circ H+\left(B_{2}+B_{02}\right) w^{\prime}\right) \circ H
$$

and observe that, if $h=H(x)$ for $x \in W_{2}$, then

$$
\begin{aligned}
f(x)= & w_{2}^{\prime \prime}(h)\left|D_{0} H(x)\right|^{2}+w_{2}^{\prime}(h)\left(\Delta_{0} H(x)+b_{0}(x) \cdot D H(x)\right) \\
& -\left(A_{2} w_{2}^{\prime \prime}+\left(B_{2}+B_{02}\right) w_{2}^{\prime}\right)(h)
\end{aligned}
$$

and

$$
\begin{align*}
\int_{0}^{T_{2}(h)} f(X(t, x)) d t= & T_{2}\left(A_{2} w_{2}^{\prime \prime}+\left(B_{2}+B_{02}\right) w_{2}^{\prime}\right)  \tag{5.1}\\
& -T_{2}\left(A_{2} w_{2}^{\prime \prime}+\left(B_{2}+B_{02}\right) w_{2}^{\prime}\right)=0 .
\end{align*}
$$

For $x \in \bar{W}_{2}$, define

$$
\chi(x)=\int_{0}^{\tau(x)} f(X(t, x)) d t
$$

It is clear that $\chi \in C^{2}\left(\bar{W}_{2} \backslash l_{1}\right)$. Moreover, recalling the notation $\tilde{\tau}$ and $U$ and the fact that either $\tilde{\tau}=\tau$ or $\tilde{\tau}=\tau+T_{2} \circ H$ in $\bar{U} \cap \bar{W}_{2}$, we obtain from (5.1) that, for any $x \in U \cap \bar{W}_{2}$,

$$
\chi(x)=\int_{0}^{\tilde{\tau}(x)} f(X(t, x)) d t
$$

and, hence, $\chi \in C^{2}\left(U \cap \bar{W}_{2}\right)$ and $\chi \in C^{2}\left(\bar{W}_{2}\right)$.
It turns out that $\chi$ is a solution of

$$
\begin{equation*}
-b \cdot D \chi=f \quad \text { in } W_{2} \tag{5.2}
\end{equation*}
$$

Indeed fix any $x \in W_{2} \backslash l_{1}$ and observe that, if $t>0$ is sufficiently small,

$$
\tau(x)=\tau(X(t, x))+t
$$

Then

$$
\begin{aligned}
b(x) \cdot D \chi(x) & =\left.\frac{\partial}{\partial t} \chi(X(t, x))\right|_{t=0}=\left.\frac{\partial}{\partial t} \int_{0}^{\tau(X(t, x))} f(X(s, X(t, x))) d s\right|_{t=0} \\
& =\left.\frac{\partial}{\partial t} \int_{0}^{\tau(x)-t} f(X(s+t, x)) d s\right|_{t=0} \\
& =-f(X(\tau(x), x))+\int_{0}^{\tau(x)} \frac{\partial}{\partial s} f(X(s, x)) d s \\
& =-f(X(\tau(x), x))+f(X(\tau(x), x))-f(X(0, x))=-f(x)
\end{aligned}
$$

i.e., $\chi$ satisfies (5.2) in $W_{2} \backslash l_{1}$ and, since $\chi \in C^{2}\left(W_{2}\right)$, it satisfies (5.2) in $W_{2}$.

Finally, we define $\zeta_{2}^{\varepsilon} \in C^{2}\left(\bar{W}_{2}\right)$ by $\zeta_{2}^{\varepsilon}=w_{2} \circ H+\varepsilon \chi$. If $u=\zeta_{2}^{\varepsilon}$, then, for some $C>0$,

$$
\begin{aligned}
& -\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) u \\
& =-\left(\Delta_{0}+b_{0} \cdot D\right)\left(w_{2} \circ H\right)-b \cdot D \chi-\varepsilon\left(\Delta_{0}+b_{0} \cdot D\right) \chi \\
& =-\left(\Delta_{0}+b_{0} \cdot D\right)\left(w_{2} \circ H\right)+f-\varepsilon\left(\Delta_{0}+b_{0} \cdot D\right) \chi \\
& =-\left(A_{2} w_{2}^{\prime \prime}+\left(B_{2}+B_{02}\right) w_{2}^{\prime}\right) \circ H-\varepsilon\left(\Delta_{0}+b_{0} \cdot D\right) \chi \\
& \leq-2-\varepsilon\left(\Delta_{0}+b_{0} \cdot D\right) \chi \leq-2+C \varepsilon
\end{aligned}
$$

Since $\varepsilon \in\left(0, \varepsilon_{0}\right)$ and $\varepsilon_{0}$ is sufficiently small, we may assume that

$$
-\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) u \leq-1 \quad \text { in } \quad W_{2}
$$

The uniform convergence of the $\zeta_{2}^{\varepsilon}$ 's to $w_{2} \circ H$ in $W_{2}$ is obvious.
We present here the
Proof of Theorem 3.3. We only discuss the case $i=2$, since the arguments for $i=1,3$ are similar.

Choose $w \in C^{4}\left(\bar{I}_{2}\right)$ (for instance, a quadratic function) such that

$$
-\left(A_{2} w^{\prime \prime}+B_{2} w^{\prime}\right) \leq-2 \text { in } I_{2}, w\left(h_{0}\right) \leq-2 \text { and } w\left(h_{2}\right)=d_{2} .
$$

Using Theorem 5.1 we find a family $\left\{w^{\varepsilon}\right\}_{\varepsilon \in\left(0, \varepsilon_{0}\right)} \subset C^{2}\left(\bar{W}_{2}\right)$ such that

$$
-\left(\Delta_{0}+\varepsilon^{-1} b \cdot D\right) w^{\varepsilon} \leq-1 \text { in } W_{2} \text { and } \lim _{\varepsilon \rightarrow 0+}\left\|w^{\varepsilon}-v\right\|_{\infty, W_{2}}=0
$$

A minor modification of the $w^{\varepsilon}$ 's yields a desired family $\left\{w_{2}^{\varepsilon}\right\}_{\varepsilon \in\left(0, \varepsilon_{0}\right)}$.
The rest of the section is devoted to the
Proof of Theorem 3.4. In view of (1.9) and (1.10), we may assume, by choosing $\kappa>0$ small enough, that $a_{11}>0$ in $S_{\kappa}$.

As in [4], we consider the function $E \in C^{\infty}(\mathbb{R})$ given by

$$
E(x)=\int_{0}^{x} e^{-t^{2}} \int_{0}^{t} e^{s^{2}} d s d t
$$

and note that, for $x \in \mathbb{R}$,

$$
E(-x)=E(x), \quad E^{\prime \prime}(x)+2 x E^{\prime}(x)=1 \quad \text { and } \quad E(0)=E^{\prime}(0)=0
$$

and

$$
\lim _{x \rightarrow \infty} \frac{E(x)}{\log x}=\lim _{x \rightarrow \infty} x E^{\prime}(x)=\frac{1}{2} .
$$

Accordingly, we can choose $C_{0}>0$ such that

$$
0 \leq E(x) \leq C_{0} \log (x+2) \quad \text { and } \quad 0 \leq E^{\prime}(x) \leq C_{0} \quad \text { in } \quad[0, \infty)
$$

and, for all $x \in \mathbb{R}$,

$$
E^{\prime \prime}(x)+2 x E^{\prime}(x)-\frac{1}{2 C_{0}}\left|E^{\prime}(x)\right| \geq \frac{1}{2}
$$

We define the function $v$ on $S_{\kappa}$ (or on the interval $[-\kappa, \kappa]$ ) by

$$
v(x)=v\left(x_{1}\right)=\alpha E\left(\beta x_{1}\right),
$$

where $\alpha>0$ and $\beta>0$ are constants to be fixed later.
Next choose constants $\mu>0$ and $\theta>0$ such that $\mu \geq\left\|a_{11}\right\|_{\infty, \Omega}+\left\|D a_{11}\right\|_{\infty, \Omega}+$ $\left\|D a_{12}\right\|_{\infty, \Omega}+\left\|b_{0}\right\|_{\infty, \Omega}$ and $a_{11} \geq \theta$ in $S_{\kappa}$.
A straightforward calculation yields that, as function of $x_{1}, v$ satisfies

$$
v^{\prime \prime}+2 \beta^{2} x_{1} v^{\prime}-\frac{\beta}{2 C_{0}}\left|v^{\prime}\right| \geq \frac{\alpha \beta^{2}}{2} \quad \text { in }[-\kappa, \kappa] .
$$

while, as a function on $S_{\kappa}$,

$$
\begin{aligned}
& \left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) v \\
& =a_{11}(x) v^{\prime \prime}\left(x_{1}\right)+\left(a_{11, x_{1}}(x)+a_{21, x_{2}}(x)\right) v^{\prime}\left(x_{1}\right)+b_{01}(x) v^{\prime}\left(x_{1}\right)+\frac{1}{\varepsilon} x_{1} v^{\prime}\left(x_{1}\right) \\
& \geq a_{11}\left(\frac{\alpha \beta^{2}}{2}-2 \beta^{2} x_{1} v^{\prime}+\frac{\beta}{2 C_{0}}\left|v^{\prime}\right|\right)-\mu\left|v^{\prime}\right|+\frac{1}{\varepsilon} x_{1} v^{\prime}(x) \\
& =\frac{\theta \alpha \beta^{2}}{2}+\left(\frac{1}{\varepsilon}-2 \mu \beta^{2}\right) x_{1} v^{\prime}+\left(\frac{\theta \beta}{2 C_{0}}-\mu\right)\left|v^{\prime}\right| .
\end{aligned}
$$

Next we fix $\alpha, \beta$ so that

$$
\begin{equation*}
\theta \alpha \beta^{2} \geq 2, \quad 1 \geq 2 \mu \beta^{2} \varepsilon \quad \text { and } \quad \theta \beta \geq 2 C_{0} \mu \tag{5.3}
\end{equation*}
$$

Indeed set

$$
\alpha=4 \mu \varepsilon \theta^{-1} \quad \text { and } \quad \beta=(2 \mu \varepsilon)^{-1 / 2}
$$

It follows that (5.3) is satisfied for $\varepsilon \in\left(0, \varepsilon_{0}\right)$, provided that $\varepsilon_{0} \in(0,1)$ is so small that

$$
\frac{\theta \beta}{2 C_{0}}=\frac{\theta}{2 C_{0} \sqrt{2 \mu \varepsilon}} \geq \mu
$$

We write $v_{\varepsilon}$ for $v$ and note that

$$
-\left(\Delta_{0}+\left(b_{0}+\varepsilon^{-1} b\right) \cdot D\right) v_{\varepsilon} \leq-1 \quad \text { in } \quad S_{\kappa} .
$$

Also, since

$$
v_{\varepsilon}(x)=\frac{4 \mu \varepsilon}{\theta} E\left(\frac{1}{\sqrt{2 \mu \varepsilon}} x_{1}\right),
$$

we find that, for some $C>0$ independent of $\varepsilon$,

$$
0 \leq v_{\varepsilon}(x) \leq C \varepsilon \log \left(\varepsilon^{-1}+2\right)
$$

The family $\left\{v_{\varepsilon}\right\}_{\varepsilon \in\left(0, \varepsilon_{0}\right)}$ has the required properties.

## 6. Appendix

6.1. Invariance under change of variables. For the convenience of the reader we record here the change of variable formula for the pde in (1.4).

Let $x=\Phi(y)$ be a $C^{2}$ diffeomorphism from $U \subset \mathbb{R}^{2}$ to $V \subset \Omega$. Assume that $u \in C^{2}(V)$ satisfies the pde in (1.4) for some $\varepsilon>0$. Then $\tilde{u}(y)=u \circ \Phi$ satisfies the pde

$$
-\operatorname{div}(\tilde{A} D \tilde{u})-\tilde{b}_{0} \cdot D \tilde{u}-\varepsilon^{-1} \bar{D} \tilde{H} \cdot D \tilde{u}=\tilde{g} \quad \text { in } U,
$$

where

$$
\begin{aligned}
\tilde{A}(y) & =\operatorname{det} D \Phi(y) D \Phi(y)^{-1} A \circ \Phi(y)\left(D \Phi(y)^{-1}\right)^{*}, \\
\tilde{b}_{0}(y) & =\operatorname{det} D \Phi(y) D \Phi(y)^{-1} b_{0} \circ \Phi(y), \\
\tilde{H}(y) & =H \circ \Phi(y), \\
\tilde{g}(y) & =\operatorname{det} D \phi(y) g \circ \Phi(y) .
\end{aligned}
$$

This can be checked by a direct computation, which we leave to the interested reader. If $\Phi$ is orientation-preserving, i.e., $\operatorname{det} \Phi>0$, then $\tilde{A}(y)$ is nonnegative definite. Otherwise, it is nonpositive definite, and, to keep the structure of degenerate ellipticity of the pde, one has to multiply $\left(\tilde{A}, \tilde{b}_{0}, \tilde{H}, \tilde{g}\right)$ by a negative constant (e.g., $-1)$, which introduces a change of the sign of the Hamiltonian.
6.2. Green's formula. We state and prove here is a simple consequence of Green's formula, which is used repeatedly in the paper.

Lemma 6.1. Let $f=\left(f_{1}, f_{2}\right) \in C^{1}(\Omega)$ and $\alpha_{i} \in J_{i}$, with $i=1,2,3$. Then

$$
\sum_{i=1}^{3}(-1)^{i} \int_{0}^{T_{i}\left(\alpha_{i}\right)}(f \cdot D H) \circ \Phi_{i}\left(t, \alpha_{i}\right) d t=\sum_{i=1}^{3}(-1)^{i} \int_{0}^{\alpha_{i}} \int_{0}^{T_{i}(h)} \operatorname{div} f \circ \Phi_{i}(t, h) d t d h
$$

Proof. If $U=\{H=0\} \cup\left\{x \in \Omega_{2}: H(x)<\alpha_{2}\right\} \cup \cup_{i=1,3}\left\{x \in \Omega_{i}: H(x)>\alpha_{i}\right\}$.
Green's formula yields

$$
\int_{\partial U} f \cdot \nu d l=\int_{U} \operatorname{div} f d x
$$

where $\nu$ and $d l$ denote respectively the outer unit vector on $\partial U$ and the line element on $\partial U$. Note that $\partial U=\cup_{i=1}^{3} c_{i}\left(\alpha_{i}\right), \nu=D H /|D H|$ on $c_{2}\left(\alpha_{2}\right)$ and $\nu=-D H /|D H|$
on $\cup_{i=1,3} c_{i}\left(\alpha_{i}\right)$ and, if the loops $c_{i}\left(\alpha_{i}\right)$ are parametrized by $x=\Phi_{i}\left(t, \alpha_{i}\right)$ with $t \in$ $\left[0, T_{i}\left(\alpha_{i}\right)\right)$, then $d l=\left|D H\left(\Phi_{i}\left(t, \alpha_{i}\right)\right)\right| d t$. Thus,

$$
\int_{\partial U} f \cdot \nu d l=\sum_{i=1}^{3}(-1)^{i} \int_{0}^{T_{i}\left(\alpha_{i}\right)}\left(f_{1} H_{x_{1}}+f_{2} H_{x_{2}}\right) \circ \Phi_{i}\left(t, \alpha_{i}\right) d t
$$

On the other hand, recalling (1.15), we find that

$$
\int_{U} \operatorname{div} f d x=\sum_{i=1}^{3}(-1)^{i} \int_{0}^{\alpha_{i}} d h \int_{0}^{T_{i}\left(\alpha_{i}\right)}(\operatorname{div} f) \circ \Phi_{i}(t, h) d t
$$

Combining these observations completes the proof.
